"I have just been reading in the Bulletin of the Imperial Department of Agriculture a very interesting account by Mr. Joseph Jones of the experimental tapping of various kinds of rubber trees in the Dominica Botanic Station, and I note that he is rather troubled by the dark colour of the produce, more especially that yielded by the Funtumia trees. In view of the great interest that is now being taken in the cultivation of rubber in the West Indies, it may be useful to some of your readers to know how the latex of rubber is treated in Uganda.

"In some of the great forests of this territory, considerable numbers of the *Funtumia elastica*, or 'Lagos Silk Rubber,' are found, and concessions for the sole right of tapping these trees are held by various companies. While visiting the Budonga Forest lately, I had an opportunity of observing the manner in which the crude latex is treated. The milk is obtained by making small 'herring-bone' incisions in one side of the trunks of the trees. These incisions are made with a V-shaped tapping tool, and reach from the base of the tree up to a height of 40 or 50 feet. *Funtumia* growing in a forest in its natural condition, has a slender, straight stem of great height, and branches only at the top. The trees are tapped every three months, so that, in each year, every side of the trunk has been made to yield its milk. The average yield of latex, at each tapping, is about one quart from each tree, and each stem may be expected to give about one pound of pure rubber per annum.

"The milk is brought at once to the factory, and is allowed to stand for a couple of days in large earthenware pots. It is then strained through pieces of red cotton, known as 'Turkey red,' for the removal of impurities. An equal quantity of water is added to the latex, and about a pint of the mixture is placed at a time in a small earthenware vessel. This small pot is then placed in a larger vessel containing water maintained at a temperature just below boiling point, after the fashion of a 'bain-marie.' Carbonate of potash is added in the proportion of 1 per cent. to the latex and water, and the mixture is stirred

* Since the date when this memorandum was prepared, the Exhibition has been opened, and is now believed to be pursuing a successful career.

with a wooden spoon until it coagulates. This usually occurs after three or four minutes. In the factory which I inspected there was a rough and ready 'range' of six small fires, so that half a dozen lots of latex could be dealt with simultaneously. Each pot, however, required the attention of one man. The carbonate of potash appears to prevent the rubber from turning to a dark colour. As soon as the latex has coagulated, the 'dollop' of rubber is taken out of the pot and placed under a press, so that all the moisture may be extracted from it. The press is very much like the sort used for taking copies of letters in offices, and being supplied with four or five boards can deal with several cakes of rubber at a time. The one I saw was worked by two men, and the pressure exerted was so great that each clot of rubber was quickly transformed into a very thin 'pancake' of creamy-white colour, each bearing the initials or brand of the company. This process very effectually extracts not only all the water, but also nearly all the resin in the rubber. The pancakes, after passing through the press, are thoroughly washed in water and placed to dry in the shade, on shelves made of reeds. The rubber gradually assumes a dark amber colour, but it is almost perfectly clean and transparent. In a few days it is fit for transport. I have much pleasure in sending you a sample of the rubber thus prepared, and would ask you, after inspection, to send it to the Curator of the Botanic Station at Dominica.

"A considerable quantity of *Funtumia* has been planted in the West Indies during the last two or three years and these notes may be of interest to the planters there. I may add that the produce of the *Funtumia*, obtained by the process above described, is now selling in London at 5s. 6d. per lb., a price almost equalling that obtained for the best Para. It has heretofore been thought that *Funtumia* rubber could not compare in value with the product of Para or of Castilloa."

OPENINGS FOR THE MOTOR TRADE IN SOUTH AFRICA.

South Africa, and especially Johannesburg and the Witwatersrand, present a most attractive field for the sale of automobiles, and one which has engaged the close attentions of motor-car manufacturers generally, with the result that large numbers of cars of all descriptions have been sold. There still, however, appear to be good openings for an increased importation. Some manufacturers seem to be quite content with an intermittent and spasmodic forwarding to South Africa of beautifully prepared catalogues. This method, while probably calling for no great outlay on the part of any one concern, is nevertheless an absolute waste of printed matter, postage and time. According to a recent report from Cape Town of the special agent of the American Department of Commerce, it cannot be said to involve a waste of time on the part of present or prospective automobile users in South Africa, for from all indications and comments it is perfectly safe to say that no one pays any attention to them. Automobiles in South Africa are not an article of luxury indulged in solely by those desiring a car for pleasure and recreation. They are necessary to the success of every man in South Africa who has relations with the mining industry, and this is proved from a slight view of the area over which the mining industry is spread. The Witwatersrand Reef extends in more or less unbroken line for upwards of seventy miles east and west, with Johannesburg approximating its centre. Many important mines are situated over fifty miles from that city. It is a daily occurrence for a mining engineer, or some officer of any of the large importing houses, to be obliged to visit a mine 40 or 50 miles or even further, and involving a run of 100 or 150 miles, which can only be accomplished by means of a motor-car. Railway and electric-car facilities, while sufficient to satisfy the demands of ordinary inter-urban travel around Johannesburg, are inelastic and incapable of affording means of transportation to the many places which daily demand the presence of those engaged in the management of the important affairs of the mines. By means of the automobile only can these points be reached. Carriages or other horse-power vehicles are unable to give the satisfaction, either in point of time or endurance obtained by the use of the automobile. In fact, so great a factor is time in supplying machinery "parts" and "spares," that in cases of emergency automobiles are often called into use in their delivery. The kind of automobile in use varies considerably according to the individual fancy, which is the result, in great measure, of the automobile experience of friends of the prospective purchaser, and also to the ability of the salesman to present the merits of his particular make. There are, however, certain basic principles or features dictated by the nature of the work which the car is called upon to perform—the physical condition of the roads over which it may have to travel, and certain climatic conditions. The average car in use along the "Reef" is selected for its ability to withstand the hard usage of the roughest roads, to climb steep gradients, and to cover a maximum mileage per gallon of petrol or gasoline. Gradients of 1 in 30 are to be met frequently in railway travel, while 1 in 14 is not uncommon for the ordinary country road. It is evident, therefore, that motors with a high hill-climbing efficiency are demanded. From fifteen miles upward per gallon of petrol are now required of new cars, although from twelve to fifteen miles is said to be the maximum of some now in use. Tho horse-power of motors ranges from 6 up to 26-30 horse-power, according to the idea of the individual, but great speed is not a deciding factor, and, in fact, high-speed cars, excepting on exceedingly rare occasions, are obliged to run on one-fourth or one-half their capacity by reason of the roughness of the roads. Steam-cars are not to be found on the Rand to any

extent. Both chain-drive and direct shaft-drive cars are popular. In chain-drive, the centre-drive chain is impossible on account of the great quantity of obstructions found, only side-drive chains being suitable. With many, however, the direct shaft-drive is preferred on account of the great amount of sand to be found in all parts of South Africa, which cuts chains so rapidly as to reduce greatly their life, and is accountable for a large number of breakages. A high clearance is absolutely imperative in all cars. A clearance of at least eleven or twelve inches is demanded, and anything greater without inducing top heaviness is a desirable feature. Four forward speed gears and one reverse gear are regarded as the essential of the best motor car along the Reef. As the climate of South Africa is exceedingly dry, with the exception of the narrow coast belt, and the rays of the sub-tropical sun are quite direct, the effect upon all wooden constructions is at once evident in motors after a few months' service. All veneering, box-work, and fittings of wooden construction are dried up, warped, and twisted out of shape. To meet this action of the climate all cars now sold have these parts finished in aluminium. Because of the heat of this latitude the air-cooled engines are valueless. According to past experience only water cooling has proved satisfactory. With regard to tyres the heaviest and best qualities only are satisfactory. The roads immediately surrounding Johannesburg, Kimberley, or any of the centres in the mining area, and in fact throughout South Africa, are only fairly well maintained at best, while within a very short distance they become mere tracks worn in the velt and in other places completely disappear. They consist of two ruts of varying depths and roughness flanking two paths worn by the hoofs of oxen or horses, while the centre is plainly marked by a ridge of from four to eight inches of rough earth and boulders, at times surmounted by a growth of rank vegetation. In many instances the trackless waste presents a far more attractive alternative than the roadway, in spite of the irregularly recurrent ant heaps, boulders and gullies. The country is essentially mountainous, or at best one of steep hills and heavy gradients, the roads not yet boasting of bridges. The register of automobiles in Johannesburg recently showed a total of 768 cars for the present year, and five years ago an automobile was a rarity. Upwards of 200 are reported by dealers to be in use in Cape Town. The prices of automobiles range from £350 upward, averaging about £400. At a moderate estimate by those qualified to judge, there is about £200,000 worth of automobiles in constant daily use in Johannesburg alone, while in the entire length of the reef at least twice the amount will be found. From information obtained from various users, the life of an automobile in South Africa is from two and a half to five years. New recruits are daily entering the ranks of motor-car owners, and a continued sale may be predicted both in supplying the places of worn-out cars and in meeting the requirements of new purchasers. It is urged that manufacturers should avail themselves of this field for the sale of motor cars by sending out salesmen directly to represent their machines, and who are competent to set forth the merits and features of their makes. They must be prepared to meet active competitors already in the field from every auto-producing country whose cars have a reputation for meeting the difficulties of South Africa motoring. There is a good sale for motor cycles, and most of those now seen are of British and German makes, the latter predominating. They range in prices from £40 to £50. While the Witwatersrand is the most profitable field in South Africa for these motor vehicles, still, throughout the different colonies, in the chief cities, there is a great interest taken in them, and sales are constantly being made. In Durban and Cape Town automobile and motor cycle clubs have regular runs, and motor enthusiasts are to be found everywhere. The value of motor vehicles imported into British South Africa, in the year ended June 30th, 1906, amounted to £172,569.

MADEIRA WICKER FURNITURE.

A considerable quantity of wicker furniture is now being made in Madeira, the osier or willow used in this industry being indigenous to the island, and scientifically known as the *Salix viminalis*. It is easy to propagate, grows freely, and has great resisting power, preferring a moist soil, though not exacting it. It is propagated by cuttings, a crop maturing in nine months. After being gathered, the ends are soaked in water until the tops begin to sprout, when it is easily peeled and ready to be worked up. The amount produced in the island is about 400 tons annually, the raw product being worth from £12 to £14 per ton. The willow when peeled is particularly white, with a silky and glossy appearance, for which it is greatly admired, although this freshness of surface does not long resist the bleaching effects of the sun. The American Consul at Funchal says it is noticeable that the finished article displays little, if any, artistic development from year to year. It is really surprising, to those familiar with the limitations of the artisans, that they have been able to show so much aptitude and delicacy of design, being altogether without examples to imitate, with little notion of design, and no educational advantages. Though they can be relied upon faithfully to execute, they can never furnish more than the mechanical skill to obey the creative instinct of others. The more common articles of furniture manufactured are chairs, retailed in Madeira from 6s. 6d. to 8s. 6d. each; sofas, from 12s. 6d. to 30s. each; tea tables, 6s. to 25s.; hampers, and a great variety of baskets, of all sizes, shapes, and colours. The exports are said to amount to at least £25,000 in value annually. The number of men employed in the industry is about 500, their pay being at the rate of 2s. a day.

HOME INDUSTRIES.

The Cotton Outlook.—In view of the sensational reports respecting the position of the cotton crop in the United States, some calculations made by Messrs. Neill Bros. are noteworthy. During the past four weeks 320,000 bales have come into sight, against an average of 315,000 for the corresponding weeks of the last four seasons. Add the average deliveries after this date of the last five seasons, namely 637,000, and the total of this season's commercial crop would be 13,697,000 bales, the largest on record. Messrs. Neill's estimate was 13,500,000, and that may be taken as roughly correct. The visible and invisible supply is expected to be sufficient for the consumption of American cotton in Europe and America up to the middle of November, against a four weeks shorter supply last year, so that if the new crop should be a month later the position of consumers would be still about the same as it was in 1906. With regard to the acreage for the new American crop, Messrs. Neill Bros. adhere to their forecast of 33,000,000 acres, which, on the basis of the minimum and maximum yields per acre during the last ten years, would indicate for 1907-8 a crop range of from 11½ to 15½ million bales, or, with an average production per annum, about 13½ million bales. But the crop has been very materially delayed by adverse weather, and a long maturing and picking season will be necesssary to ensure a good result. Invitations have been received from the National Association of Cotton Manufacturers, Boston, by various cotton employers associations in Lancashire to attend the International Conference of cotton growers, spinners, and manufacturers which is to be held at Atlanta, Georgia, United States of America, on October 7th, 8th, and 9th inst. A circular conveying this invitation states that "the purpose of this Conference is similar to that of the one held at Washington, May 1st and 2nd, 1906, in which it proposes to deal with the numerous questions as to the relationship between growers, dealers, and manufacturers of cotton." Arrangements are being made for a special train traversing the cotton-growing districts of the country, visiting some cotton mills, and also the principal American cities. The delegates will probably find ample confirmation of the opinion that the conditions under which the American cotton is picked, baled, marketed, and transported leave much to be desired. We are accustomed to associate the latest inventions and most up-to-date methods with American industrial enterprise, but the cotton business would seem to be exceptional. Old-fashioned gins and cumbersome compresses are still common. At the International Cotton Congress the American delegates were told that many of their large compresses are only fit for the scrap heap, and were advised to purchase compresses of the kind used in India and Egypt. The American bale is loosely packed, and has little more than half the density of the Egyptian bale. Its bulkiness increases the cost of carriage, it is more liable to become damp, and it is more subject to fire. The American delegates to the Congress admitted the justice of much of this criticism, but pleaded that they were doing their best to introduce a better state of things, and asked for the co-operation of European spinners. One of the objects of the autumn visit mentioned above is to devise means of making more direct the communications between the growers and the firms who spin cotton.

Fire Insurance.—It may be said roundly that the Insurance fire funds lost in 1906, owing to the San Francisco disasters, the increases of the previous three years. The total fire funds, exclusive of capital, decreased by £6,360,742 to £27,753,488, or rather less than three years profits. In 1903, after providing for dividends, the funds of the companies were increased by £2,989,000, in 1904 by £797,000, and in 1905 by £3,282,000, in all £7,068,000; while the decrease in funds during 1906 was £6,360,000. The heaviest decrease of the year in fire funds was that of the London, £690,846, followed closely by the London and Lancashire £643,667, next by the Royal Exchange £569,580, the Royal £532,585, the Phœnix £476,089, the Caledonian £444,337, and the North British £403,422. If the losses of the companies whose figures have not yet been issued are added to the known losses, and also those of the New Zealand, British American, and Western (of Toronto) Companies are added, the total net payments of British and Colonial fire insurance companies in San Francisco reach nearly eleven millions. But it is noteworthy that in proportion the smaller companies suffered most. For example, the deficit of the Alliance, after providing for claims and expenses, was only £232,865, the Caledonian £426,881; the one being 18·12 per cent. of premiums, the other 97·04. The only company transacting foreign and colonial business that made a profit in 1906 was the Guardian which withdrew from the United States some twelve years ago. If the essential principle of insurance finance is that dividends should be primarily based on interest earnings—and it is the principle upon which the best British insurance companies rest—it would seem that dividends will have to be reduced. The interest receipts, less tax and fixed charges, taking twenty-four chief companies for 1906, amounted to £1,368,614, an increase of £47,523 upon the previous year, whereas the dividends to be paid on account of 1906 amount to £2,030,724, an increase of £11,917,99 as against 1905. It may seem strange that in a year which saw the fire funds of these companies reduced by more than six millions there should be an increase in the interest on investments of £47,523, but the explanation is that although the San Francisco losses were incurred in April, 1906, they were not settled and paid until much later in the year, and the interest accruing in the interval appears in the accounts.

Insurance against Strikes.—The practice of insuring against financial loss due to strikes or lock-outs is being tried both in Germany and Austria. An

association of employers has just been formed in Bavaria for this purpose. It is open to all employers in the country, and the premiums paid are reckoned according to the total wages bill of the year, at the rate of three marks per thousand. In case of a strike the employer addresses a demand for compensation to the society, which is assisted by a committee. If the demand is valid the employer receives a grant of 25 per cent. of the average wages of each striker for each day the dispute lasts. Since in the case of an extensive strike the company might soon come to the end of its means, the claims are not settled until the end of the business year, and the rules provide that not more than a certain maximum shall be paid. Further provision against such a contingency is to be made by the accumulation of a large reserve fund. It will be interesting to follow the working of these associations. The difficulties in their way would appear to be considerable.

The Scottish Shalefield and Oil Industries.—A correspondent of *The Times* gives some notable figures relating to this industry. An estimate of the quantity of crude oil distilled in Scotland during 1905 is 57,350,000 gallons, and of the sulphate of ammonia manufactured at the works 47,000 tons. The approximate value of the various products obtained from the shale is at present only about one-third what it was in 1873, notwithstanding the improvements made in distilling and refining the oil, and in the recovery of the ammonia. The value of the shale at the mine mouth has decreased very much. In 1873 it was 10s. per ton, in 1905 it had fallen to 4s. 9d. per ton. The output over the whole of Great Britain has increased from 524,095 tons in 1873 to 2,496,785 tons in 1905; but whilst the 1873 output was valued at £262,047, that of 1905, which was nearly five times as great, was of very little more value, £593,334. Of the total output 2,493,051 tons came from Scotland in 1905; but Scotland produces only about one-fifth of the quantity of petroleum imported, which occurrs as a natural oil in America, Russia, and elsewhere. In 1905 the total import was 300,110,335 gallons, of which 68,493,036 gallons came from Russia, and 206,718,108 gallons from America. The fall in price, and the keen foreign competition, has been disastrous to the companies engaged in this industry. In 1873 there were fifty-one companies, now there are only seven. Within the past eighteen years over one and a half million pounds have been lost to shareholders. The capital at present engaged in the oil industry is slightly over £1,600,000, four-fifths of which is represented by three companies. These companies have had to reckon not only with falling prices and foreign competition, but with the gradual exhaustion of higher-grade shales; and if their position to-day is comparatively satisfactory, it is due to most careful management, and the skill and enterprise of their chemists and engineers.

Railway Fares.—It was recently intimated in these Notes as likely that a working arrangement would be arrived at between the companies engaged in the passenger traffic of the metropolis which would result in a revision of fares, having for its object some increase in the longer distance fares. An agreement has now been arrived at between the District Railway, the Metropolitan Railway, the Central London, and tube companies, which will affect fares between Hammersmith, the West-end, and the City. The Central London fares will be increased to threepence for the longer distances, and those of the Metropolitan and District will also be revised. The omnibus companies, both horse and motor, are at present outside the agreement, and it remains to be seen whether they can be persuaded to consent to a working arrangement. Although the question of fares presents difficulties in many parts of the country, the situation is most acute in London, where competition is keen and capital charges higher than elsewhere. In the country practically there are only two competitors, the railway and the tramway; in London there is a third, the motor omnibus. Many of the present fares in London are at the rate of less than a halfpenny per mile. In some provincial towns this scale leaves a profit upon working, but there working expenses are much lower. In London most of the tube lines are capitalised at from £600,000 to £800,000 per mile, and to get any dividend it is necessary that they should be earning revenue for sixteen or eighteen hours a day to the extent that is physically possible. With them working expenses are low; on the other hand, the motor 'buses which compete with them have a low capitalisation and high working expenses. They have nothing to construct but a car shed and a repair shop, but their working expenses are enormous—how high has, perhaps, still to be realised. As to the electric tramways, they also have low working expenses, but they suffer from high capitalisation owing to the use of the conduit system of construction. The tracks in the county of London alone cost about £35,000 per mile, and equipment, rolling stock, power-stations, sub-stations, &c., about as much more. It is only the horse omnibuses of London that enjoy both low capitalisation and low working expenses, and they will soon be things of the past. The only remedy, if the shareholders in the passenger-carrying companies are to get dividends, is to raise fares to a slight extent. Taking the five leading companies, the Metropolitan, District, Central London, City and South London, and North London, an average increase of a farthing a passenger would produce almost enough to raise ordinary dividends by 2 per cent., the outcome of the farthing on the basis of the passengers carried in 1906 being £278,530, and the amount required to pay the 2 per cent. £309,500. In the case of the District, which on the basis named would be benefited by the additional farthing to the extent of £65,500, the increase would be hardly sufficient to dispose of the present deficit in the fixed charges, but with the other companies named it would restore ordinary dividends to something like a reasonable level.

CORRESPONDENCE.

LUSTRE POTTERY.

SIR,—In the course of Mr. Burton's most valuable and interesting paper upon the above subject he remarks: "The beautiful ruby-red stain [of the Gubbio Potteries], which is given by the penetration of the copper vapours into the glaze, is much more pronounced. It has been suggested by many writers that the ruby-red was a secret of the potters of Gubbio, and that all the pieces of it which occur have been lustred in that town. We had no means of knowing whether such a belief is well founded or not, but it is certain that the Gubbio potters made great use of the ruby stain, and that in fact they used it as much for its beauty of colour as for its lustre quality."

In this connection it may perhaps not be without interest to note that the late Dr. J. Forbes Watson once handed to me a few small fragments of Gubbio "ruby" lustre ware, with the request that I would endeavour to ascertain to what metal or compound the fine red colour was due. My examination proved that in this instance the red stain was unquestionably due to the presence of gold, although an extremely minute trace of copper was also detected—probably only occurring as an impurity or alloy in the former. This, of course, partly answers Mr. W. C. Hancock' query as to analyses of lustre pottery.

To my thinking there is no evidence that any of the old Italian lustre "stains" were imparted by gold (or, for that matter, copper, or any other metal) present in the ware *as* such, *i e.*, in the metallic state. In fact, not only chemical tests, but microscopical, and, especially, spectroscopical ones also, quite negative such an assumption. Hence it seems probable that a silicate, or oxy-silicate, may the determining factor, or (considering that I have never yet come across a bit of the ware in question quite free from boron), more likely still, a boro-silicate of the metal.

W. LASCELLES-SCOTT.

GENERAL NOTES.

NEW ZEALAND FLAX AT THE AZORES.—Last year *phormium tenax*, or New Zealand flax, was exported from the Azores to London to the amount of 88 bales. Mr. Consul Read, in his report on the trade and commerce of the Azores in 1906, says that a great development is in store for the industry, as the cultivation of this useful plant is one which demands little labour, a very important consideration labour in the islands being scarce and consequently expensive. An American engineer is sending from the United States four machines for extracting the fibre, for which a Hamburg firm have offered £30 per ton.

HAWAII.—British trade with Hawaii has been seriously affected by the American annexation. When the Organic Act for the government of the islands came into force in June, 1906, the import trade from the United Kingdom that had, under the Hawaiian tariff, amounted to £257,545 in 1895, and, in anticipation of the imposition of the United States tariff, had risen in 1899 to £354,931, dropped to £64,317 for the fiscal year ended June 30th, 1901. The average of the three years up to June, 1905, was £98,157 only; 1904 having given the highest record. For the year ended June, 1906, the value of imports from the United Kingdom fell to £87,399. Mr. Consul Layard, from whose report (Cd. 3283) these figures are taken, says that manufacturers in the United Kingdom still persist in making up their goods for the Hawaiian market in paper, and stamping with sizes that are not in use in the United States. American trade demands absolutely that hosiery and ready-made goods be boxed in the manner, and numbered as to the sizes, called for by the United States.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 24...British Architects, 9, Conduit-street, W., 8 p.m.

TUESDAY, JUNE 25...Hellenic Studies, in the Rooms of the Society of Antiquaries, Burlington-house, W. 5 p.m. Annual Meeting.

Faraday Society, in the Library of the Institution of Electrical Engineers, 92, Victoria-street, S.W., 1. Messrs. W. R. Bousfield and T. Martin Lowry, "The Thermo-Chemistry of Electrolysis in Relation to the Hydrate Theory of Ionisation." 2. Dr. James C. Philip, "The Influence of Non-Electrolytes and Electrolytes in the Solubility of Gases in Water. The Question of Hydrates in Solution." 3. Dr. A. Findley, "The Dissociation of Hydrates as Indicated by their Equilibrium Curves." 4. Dr. George Senter, "Hydrates in Solution: Discussion of Methods Proposed for Determining Degree of Hydration." 5. Discussion on "Hydrates in Solution."

Anthropological, 3, Hanover-square, W., 8½ p.m.

WEDNESDAY, JUNE 26...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4 p.m. Annual General Meeting.

Royal Society of Literature, 20, Hanover-square, W., 8½ p.m.

British Astronomical, Sion College, Victoria-embankment, E.C., 5 p.m.

THURSDAY, JUNE 27...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

FRIDAY, JUNE 28...East India Association, Caxton-hall, Westminster, S.W., 4 p.m. Mr. J. B. Pennington, "Indian Administration: Suggestions by an Old District Officer."

Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

Physical, in the City and Guilds' Central Technical College, Exhibition-road, S.W., 5 p.m. Mr. J. T. Irwin, Demonstration of the uses of his Hot Wire Oscillographs and Hot Wire Wattmeters. 2. Mr. J. S. Dow, "A Cosine Flicker Photometer." 3. Mr. J. S. Dow, "Some Phenomena in Colour Vision." 4. Prof. W. E. Ayrton and Mr. T. Mather, Description and Exhibition of Students' Apparatus for Measuring Permeability and Hysteresis, 5. Prof. W. E. Ayrton and Mr. T. Mather, "Design of Chokers."

Journal of the Society of Arts.

No. 2,849. VOL. LV.

FRIDAY, JUNE 28, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

CONVERSAZIONE.

The Society's Conversazione will be held, by arrangement with the Council of the Royal Botanic Society, in the gardens of that Society, Inner Circle, Regent's-park, on Tuesday evening, July 9th, from 9 to 12 p.m.

The central portion of the gardens only will be used. The Conservatory and the Club house will be open.

The reception, by Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Chairman, and the other members of the Council, will be held at the entrance to the Conservatory, near the Broad-walk, from 9 to 10 p.m.

The Tropical-house, containing the Giant Water Lily (Victoria Regia), and other interesting tropical plants, will be open to visitors, and will be specially illuminated for the occasion.

An Exhibition of Growing and Cut Roses and other Flowers will be arranged in a marquee in the grounds by Messrs. W. Paul and Sons, of Waltham-cross.

A Selection of Music will be performed by the String Band of the Royal Marine Light Infantry (Portsmouth Division) in the Conservatory, and by the Band of H.M. Coldstream Guards in the Gardens, commencing at 9 o'clock.

A "Watteau" Pastoral Play in three acts, entitled "La Marquise," will be performed in the Gardens by Mr. Patrick Kirwan's Idyllic Players, commencing at 9.30 p.m.

A Concert and Entertainment, under the direction of Mr. Patrick Kirwan, will be given in the Club-house at 9.45 and 10.45 p.m.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. These tickets have now been issued. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the conversazione. On that date the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

Further particulars as to the musical and other arrangements will be given in the Programmes, which will be distributed on the evening.

PROCEEDINGS OF THE SOCIETY.

ANNUAL GENERAL MEETING.

The Annual General Meeting for receiving the Report of the Council, and the Treasurers' Statement of Receipts and Payments, during the past year, and also for the Election of Officers and New Members, was held, in accordance with the By-laws, on Wednesday last, the 26th inst., at 4 p.m., SIR STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., Chairman of the Council, in the chair.

The SECRETARY read the notice convening the meeting, and the minutes of the last annual meeting.

The following candidates were proposed, ballotted for, and duly elected members of the Society:—

Alby, Amédée, 80, Boulevard Flandrin, Paris, France.

Bacon, George Morgan, 159, Pierpont-avenue, Salt Lake City, Utah, U.S.A.

Bacon, James Hayward, Engineering Department, Grand Trunk Pacific Railway, Prince Rupert, British Columbia, Canada.
Berquist, A. S., M.Am.Soc.C.E., 1571, 47th Street, Brooklyn, New York, U.S.A.
Bovey, Henry Taylor, M.A., LL.D., F.R.S., M.Inst.C.E., Dean of the Faculty of Applied Science, McGill University, Sunandene, Montreal, Canada.
Bromley, H., George, Cape Colony, South Africa.
Conchie, James, 13A, Porchester-terrace, Hyde-park, W.
Dallas, Arthur, Messrs. Atkinson and Dallas, 4, Peking-road, Shanghai, China.
Desmond, Veterinary-Surgeon J., Adelaide, South Australia.
Dixon, John, 7, Curzon-street, Maryport.
Escudier, John L., 8, Woodstock-road, Chiswick, W.
Gautier, William Lord Albert, Prescott-lodge, Park-hill, Clapham, S.W.
Graham, Walter Armstrong, The Residency, Kelantan, Siamese Malay States.
Harrison, William James, Revenue Cruiser *Chuentiao*, care of Imperial Chinese Customs, Shanghai, China.
Hayakawa, Senkichiro, 69 Nichome, Nagatacho, Kojimachi-len, Tokyo, Japan.
Hepburn, Arthur E., 956, Nicola-street, Vancouver, British Columbia, Canada.
Jervey, Major Henry, U.S. Engineer Office, Mobile, Alabama, U.S.A.
Lindley, William Heerlein, M.Inst.C.E., 29, Blittersdorffsplatz, Frankfurt-am-Main, Germany.
Loveless, Thomas Henry, 76, Harley-street, W.
New Zealand, The Secretary, Education Department, Wellington.
O'Ryan, William, Waipiro Bay, New Zealand.
Osment, Harry Shorthose, care of British Vice-Consul, Lima, Peru, South America.
Pendleton, William B., The Corrimal Balgownie Collieries, Limited, Corrimal, New South Wales, Australia.
Pope, Alfred Atmore, Hill Stead, Farmington, Connecticut, U.S.A.
Powell, Charles, 70, Camden-road, N.W.
Richardson, Harry, The Cottage, Craigie, Broughty Ferry, N.B.
Schlicht, Paul, St. James's-court, Buckingham-gate, S.W.
Sinclair, J. E. Tanjong Pagar Dock Board, Singapore, Straits Settlements.
Singh, Sardar Sahib Ram, Mayo School of Art, Lahore, Punjab, India.
Smith, J. Landreth, Glenfield, St. George's, Grenada, British West Indies.
Stewart, William Thomas, A.M.I.E.E., Central Station, Bodinayakanur P.O., S. India.
Tan Kheam Hock, 85, Cecil-street, Singapore, Straits Settlements.
Tuxford, Ivon, Shanghai-Nanking Railway, Shanghai, China.
Underwood, Edward, Thorndon, Baldock-road, Letchworth, Herts.
Vandeleur, John Frederick Boyle, 3, Dineen-building, Toronto, Canada, and 18, Salisbury-road, Hove, Sussex.
Walsh, Edmund, J., 402, O'Connor-street, Ottawa, Canada
Wyon, Allan G., 2, Langham-chambers, Portland-place, W.

The CHAIRMAN nominated Mr. J. H. Monk and Mr. H. Conradi scrutineers, and declared the ballot open.

The SECRETARY then read the following

REPORT OF COUNCIL.

I.—ORDINARY MEETINGS.

Previous to Christmas there were five Ordinary Meetings. At the first of these—on the 21st November—Sir Steuart Colvin Bayley, the Chairman of the Council, delivered his Opening Address. The subject which Sir Steuart adopted was the History and Work of the Indian Section of the Society. It is now nearly forty years since the Section was founded, the first meeting in connection with it having taken place in February, 1869. Sir Steuart showed how useful the work of the Section had been in disseminating a knowledge of Indian matters, and in educating public opinion by papers and discussions. Believing that the Indian Section had had a fairly useful and successful life, he was not able to suggest any alteration in its constitution, or any method by which its work could be improved. He discountenanced any suggestion that the Section should break off from the parent Society and form a separate association ; but on the other hand he thought that the Section might usefully absorb the other societies now dealing with Indian matters.

At the first meeting after the opening meeting, Mr. John William Gordon read a very valuable paper on "Patent-law Reform." The first part of the paper contained an interesting sketch of the growth of Patent-law in this country, the first country in which any law of the sort was established. Referring to the great Patent Act of 1852, he took occasion to regret that the proposal inferentially contained in it for a full system of Colonial Registration was never carried into effect, the result being that each Colony now has its own Act and its own separate Patents, so that the various divisions of the Empire are now, as regards Patent-law, separate countries,

and an inventor is in the same position with regard to the Colonies as he is with regard to independent countries. Mr. Gordon devoted a large portion of his paper to the very important question of compulsory licenses and compulsory working, and it was these two topics which were principally dealt with in the discussion, and in the adjourned discussion which was held on the 16th of January, the first meeting after Christmas. The opinions expressed certainly varied; but the meeting was practically unanimous as to the necessity for some change in the system which would prevent a foreigner with an English patent from stopping the manufacture in this country, while he developed his invention, and possibly the industry dependent upon it, abroad. Mr. Gordon also spoke rather strongly as to the use of injunctions, and the readiness with which they are now granted by the Courts.

At the third meeting of the session Sir Charles Watson brought forward some of the objections which exist to the compulsory introduction of the Metric System. As a rule the advocates of the Metric System have been by far the most energetic, and most of the papers which have been read on the subject here and elsewhere have been in its favour. This was the case with the last paper on the subject read before the Society of Arts by Mr. A. Sonnenschein in 1903. Sir Charles Watson began with some account of the origin of the system, and dwelt on the discrepancies existing between the system now actually in use, and the theoretical system originally proposed. He also referred to the many difficulties of change, and the serious questions which would arise if the Metric System were to be extended into the textile and other industries. In the discussion both sides were represented. The Chairman—Sir David Gill—is well known as an advocate of the metre, and so of course is Lord Kelvin, who, as he was unable to be present, wrote criticising Sir Charles Watson's paper, and pointing out that in the improbable event of all the existing copies of the standard metre being destroyed, it would be possible to obtain a fresh standard by purely optical methods.

At the next meeting Mr. Cecil Hooper drew attention to the serious injury which is now being done to fruit and other crops by the over-protection of birds in this country. Mr. Hooper is himself a practical fruit-grower, and he produced a great deal of evidence of the very serious damage to fruit crops done by birds. He went very fully into the question, discussing both the harm done, and the assistance rendered, to the farmer by a large number of the commoner birds. Though some of the speakers in the discussion thought that the birds on the whole did as much good as they did harm, the general feeling certainly was that the growth, at all events, of fruit in this country was rendered extremely difficult and unprofitable by the damage done by birds.

At the last meeting before Christmas Mr. Albert Humphries, the President of the Association of Millers, read a most comprehensive and useful paper on "The Modern Developments of Flour-Milling." It is common knowledge that very great alterations have been made in modern methods of manufacturing flour, but what these changes actually are is certainly not generally known, except among experts. Mr. Humphries' paper gave a clear and quite popular description of modern methods. In conclusion, he strongly controverted the notion that modern developments of flour milling were harmful to the consumer, and maintained that the flour produced by the most highly developed machinery had a greater dietetic value than the flour produced by the old-fashioned mill-stones.

As mentioned before, the first meeting after Christmas was devoted to the adjourned discussion on Mr. Gordon's paper on "Patent Law Reform." At the second meeting in January, Monsieur Bunau-Varilla, who was formerly Chief Engineer of the Panama Canal Company, read a most elaborate and valuable paper on the Panama Canal. Mr. Varilla's paper was, throughout, a strong recommendation of what he terms the "Straits of Panama" type as against the "Lock Canal" type. What he advocates is, in fact, a waterway without locks, from the Atlantic to the Pacific, of an average width of 650 feet, about the width of the Thames at low tide at London-bridge. This waterway he proposes to construct almost entirely by means of dredging. To enable the dredgers to get at their work at the higher levels he proposes to dam up the rivers of the isthmus so as to form a lake. This, in addition to bringing the dredgers to their work, would form a dumping ground for the waste material. A certain small proportion, but only a small proportion, at the summit would have to be excavated in the dry, and even here the removed material could be dumped into the lake. The methods by which it is proposed to carry out the work are described in considerable detail in the paper, the estimated

cost of the work is given, and the objections to the scheme are met. It might be added that the paper was written throughout by Monsieur Varilla in English, and read by himself.

At the next meeting Mr. James Parsons gave an account of the successful attempts which have been made in Whitechapel to carry out a system of Apprenticeship. In Mr. Parsons' opinion the Apprenticeship system is by no means really dead, as it is believed to be in many quarters, and he gave an account of the useful work which has been done by the Committee with which he is associated, and also by the Jewish Board of Guardians in keeping alive the old system of Apprenticeship.

The next paper was by Mr. Thomas Young on "The Principles and Practice of Insurance." In recent years a good many developments have taken place in the methods of insurance, especially of life insurance. These new methods were fully discussed by Mr. Young, and much information given of a character likely to be useful to those who are contemplating insurance.

Amongst the many important questions which go to make up the problem of London traffic the use of motor omnibuses is one of the most important, and consequently the paper read on that subject by Lord Montagu of Beaulieu was extremely appropriate and well timed. Lord Montagu is known as a great authority upon motors, and naturally he is strongly in favour of the motor omnibus, both in London and as an adjunct to railway transport in the country. In his view, and his opinion was supported by the Chairman, Mr. Campbell Swinton, the motor omnibus, after a little more experience, will prove to be a cheaper and more valuable means of transport than the tram. The subject is one on which it is difficult to obtain accurate information, since the only persons who possess that information are the directors and managers of the various rival companies, and they are naturally precluded by their interests from publishing it. Lord Montagu's paper was therefore of much practical value.

Of recent years there have been a good many papers and lectures on the production of cold, and its remarkable applications. In his paper on "The Commercial Application of Refrigeration," Mr. Hal Williams brought the subject up to date, and showed how numerous are the applications of cold storage which have been introduced of recent years. Though the preservation of food is still the most important, it is now only one in the long list of industrial uses to which refrigeration is put. Amongst the most remarkable of its applications, if not the more important, was certainly the power which is now given to horticulturists to retard the development of plants by cold, so as to produce flowers or fruit almost at any season of the year.

The subject of Type-writers has received a good deal of attention at the Society of Arts. When the modern type-writer was first being brought into popular use, Mr. John Harrison described the forms of machines which were employed in 1888, while as far back as 1867 Mr. John Pratt described at one of the Ordinary Meetings of the Society the very ingenious writing machine he had invented. The history of the apparatus has also been fully dealt with in the course of Cantor Lectures by Mr. H. C. Jenkins, who traces the origin of the machine as far back as 1714. In the paper which Mr. Arthur E. Morton read in March last on Modern Type-writers, the various machines now in use were fully described, with the numerous detailed additions which have been made to them of recent years. Probably few, except expert typists, know how much can be done by the modern apparatus, especially in the way of copying and keeping accounts, and in varying the colour of the printing.

In his paper on "The Discovery of the South-Eastern Coalfield," Professor Boyd Dawkins gave a very full account of the history of the investigations into the existence of coal in Kent since Godwin-Austen in 1856 suggested the possible extension of the coal seams beneath the south-eastern part of England. He also showed precisely the present condition of the undertaking, and held out good grounds for hope that before very long the coal supplies of the country would be augmented by the coal from the south-eastern field, which he believed to be valuable and workable. This field he considered would probably rank, when fully developed, among the important coal-fields, and cause centres of industry to be established in Kent like those of Liége and Valenciennes.

For some little time past Mr. Noel Heaton has been engaged upon a careful investigation into the character of the stained glass used in mediæval windows, its character, and the causes of its decay. The results of these investigations were given to the Society in an interesting paper read by him, in which he

threw a good deal of light on the technical problems which face the modern glass-painter and glass-maker.

The perennial problem of London smoke was once more treated by Mr. J. B. Kershaw, with special reference to the prevention of smoke in factories and electric supply stations. He urged that the prevention of smoke under such conditions was, with a properly designed plant, entirely possible, and urged that steps should be taken to insist on the application of scientific principles to this branch of industrial practice.

At the first meeting after Easter Mr. Louis Felberman, who has established a well-deserved reputation among his compatriots for the efforts which he has been making, as Acting Vice-President of the Hungarian Society, for making Hungary better known in this country, and developing a good feeling between the two kingdoms, read a paper on "Arts and Industries in Hungary in Ancient and Modern Days," in which he described, in a full and interesting manner, the ancient arts and the modern resources of that great country.

At the next meeting, Major Baden-Powell read a paper on "Aerial Navigation," which was the occasion of the last appearance at the Society of Sir Benjamin Baker, who was in the chair, and whose recent death the Society has so much reason to deplore. The paper dealt entirely with mechanical methods of navigating the air, excluding not only balloons, but navigable airships that relied upon gas for their power of elevation. The author would not admit that the problem of mechanical flight offered any insurmountable difficulty, though it had not yet been solved. With the engines now available all that was wanted was a hull of proper shape and construction. That such a hull would eventually be constructed had, he thought, been shown by the action of small models.

At the following meeting Mr. Herbert Wright gave a valuable and elaborate paper on "Rubber Cultivation in the British Empire." Until lately the whole of the world's supply of rubber was derived from wild trees, but, as is well known, of late years great efforts have been made in almost all parts of the world, suitable for its cultivation, to develop plantations of rubber, and though the proportionate amount of cultivated rubber is still practically insignificant, it is rapidly developing, and may be expected before many more years are passed to rival, if not to overtake, the present wild supplies. Mr. Wright, who spoke from a considerable knowledge and great practical experience of rubber cultivation, dealt with the matter very fully and completely.

At the first meeting in May Mr. Alfred E. Carey dealt with the question of "The Protection of Sea Shores from Erosion," a subject which has for centuries been one of importance to these islands, and is now actually under the consideration of a Royal Commission. Mr. Carey's was a useful, practical paper, dealing with the various methods of protecting the shore, and with the general system of administration which was, in his opinion, required to ensure the security of the whole of our coasts.

Mr. Paul Schlicht in his paper on "The Production of Coke and its Application in Domestic Fires" dealt partly with the same snbject as that already treated by Mr. Kershaw—the Prevention of Smoke—though from another standpoint. Mr. Schlicht's cure for the evil is the use of suitable coke instead of bituminous coal. He described methods for the production of such coke, and also a system which he found effective for burning it in domestic fires.

The last paper of the session was by Dr. Herbert W. G. Macleod on "Trypanosomiasis, or Sleeping Sickness," a disease which, as is well known, has been devastating certain districts of Central Africa. Mr. Macleod dealt with the subject in the only manner suitable for the Society of Arts, where, of course, such purely medical subjects can only be treated in a popular fashion. It is one special provision of the Society to help to form and educate public opinion on such topics. Unless information on such subjects is brought before the general public, it is idle to hope that influence will be brought to bear upon the Government, such as is required to induce them to take the necessary steps for the investigation into the causes of tropical diseases like Trypanosomiasis, and its necessary prevention.

II.—Indian Section.

Unflagging interest continues to be manifested in the transactions of this Section, and since its formation, some forty years ago, it has probably had not had a more successful session than the one just terminated. If more attention is now bestowed by the public at home upon our great Asiatic dependency, and if Indian subjects have to a considerable extent ceased to be "not only insipid, but positively distasteful," the Society of Arts may claim to have done not a little in the bringing about of this

desirable change. An authority on India has recently written :—"The Society fulfils a most useful *rôle* in providing an adequate opportunity for the discussion of Indian problems—often of the highest Imperial interest—before interested and influential audiences."

An occasion of special importance was the meeting at which Sir Frederic Lely read a remarkable paper on the famine in Gujerat, and Lord Curzon of Kedleston presided. His Lordship, when invited to take the chair, replied that though living in the country and in retirement he would, out of regard for Sir F. Lely, accede to the Committee's request, and in opening the meeting Lord Curzon said that he could not resist the invitation, which he almost regarded as a command. Sir Charles Elliott, in 1897, and Mr. Holderness, in 1902, addressed the Society on Famine. Sir Frederic Lely dealt with the subject from a different point of view. "They," he said, "discussed the problems of famine policy as they appear from the watch-tower of the Imperial Government. I essay the humbler task of giving some reminiscences of one who was down below in the thick of the fight." In the course of his paper, so full of eloquence and pathos, as the Chairman described it, the author combated the theory which blames the British *raj* for the recurrence of famine and the disaster it entails. He pointed out that our predecessors in the Government thought so little of famine that they did not take the trouble to record it, but he was able to quote authentic evidence of sixteen famines in one part of India alone—the Presidency of Bombay—between 1770 and 1825. Famine has ever existed in India. It "once meant abandonment of the people, desolation, cannibalism. It now means much distress, much mortality it is true, but also persistent and thoughtful effort to diminish it, approaching by dint of severe experience ever nearer to the ideal when everything shall be foreseen and forestalled." The paper brought out the striking fact that famine was not due to inability to bring grain to the locality, but to want of means of purchasing it when it was brought there. Lord Curzon, in opening an interesting discussion, testified to the truthfulness of Sir F. Lely's picture of the state of things that prevailed during periods of scarcity before England took over the government, and advised those who wish to see what the British Government is capable of doing in India to go there not in prosperous times, but when the land is in the throes of a great famine.

Intimately connected with the subject of Famine is that of Irrigation. In 1896 Sir James Lyall read a paper on "Punjab Irrigation—Ancient and Modern," and more recently Mr. Sidney Preston dealt with the latest developments, particularly the great Chenab Canal scheme. It remained for some one to supplement these valuable contributions by showing exactly how the work of the engineers has been utilised and how, as the result of their splendid achievements, large and thriving communities have been planted on what until a comparatively recent period were vast arid tracts uninhabited except by nomads. Mr. Laurence Robertson, I.C.S., who assisted in the organisation of one of the settlements, consented to prepare such a paper, and this paper under the title "Irrigation Colonies in India," was read before a very appreciative audience on May 30th, the Under-Secretary of State for India, Mr. C. E. Hobhouse, M.P., presiding. The colonies described in Mr. Robertson's excellent paper are three in number—two, the Chenab and the Jhelum, being in the Punjab, and the third, the Jamrao, in Sind. The largest, the Chenab, commands an area of 5,000 square miles and the colonies altogether are equal in extent to the whole of the culturable area in Egypt. In 1905-6 canal water was supplied to over 2½ million acres, and Mr. Robertson estimates the value of the crop raised at nearly 6 millions sterling, almost double the gross capital cost of the systems. Agricultural land which at the beginning of operations on the Chenab fetched under £3 an acre now sells for £20 or £30. The progress of most of the towns in the colonies has been rapid. When the last census was taken, in 1901, Lyallpur had a population of over 10,000, although the town had no existence six years before. Communications, however, are not yet quite satisfactory and Mr. Robertson recommends the construction of light feeder railways. The suggestion is supported by Sir Thomas Higham, who thinks such railways likely to be very remunerative. An exceptionally interesting discussion followed the reading of Mr. Robertson's paper, the speakers being Sir Evan James, Sir Frederic Lely, Mr. H. S. Lawrence, I.C.S., Mr. T. W. Holderness, Mr. T. H. Thornton, and the following engineering authorities :—Mr. J. S. Beresford, C.I.E., Mr. R. B. Buckley, C.S.I., and Colonel Sir Colin Scott-Moncrieff.

An analogous subject was ably dealt with at an earlier meeting by Sir Edward C. Buck, late head of the Agricultural Department in

India. In 1906 he was charged by Lord Minto's Government with a mission to visit Italy to report upon the methods by which river silt is so successfully and extensively utilised in that country for the fertilization of previously sterile tracts, and for the prevention of malaria. In his paper Sir Edward set forth the results of his exhaustive investigations and discussed the possible application of Italy's "grand object-lesson" to India. He took for his text a resolution of the Agricultural Conference held at Ravenna three years ago, "that wherever fertilizing silt is available it is a grave economical error not to profit by it," and he sought to demonstrate that in no country is the application of that proposition more needed than in India. In the discussion that followed a general desire was expressed for further inquiry by the Indian authorities.

Not the least valuable of the series of papers on the provinces and capitals of India was contributed by Sir James Thomson, whose subject was the city of Madras, on whose charms the Chairman of the meeting (Lord Ampthill) and Sir Philip Hutchins also spoke with enthusiasm. The third city in India and the seventh in the whole Empire—the marvel of Madras to Sir J. Thomson is that with so little granted by natural position so much has been accomplished. "Madras has no mighty river flowing past, no supremely fertile soil adjacent, no splendid bay, no hills to look up to or from." But, as the author indicated, her development is happily unhindered by circumstances that make government a less easy matter in other centres of British power in the peninsula.

An admirable paper by Mr. A. Yusuf Ali, I C.S., on the Indian Mohammedans, was the first of a course on the peoples of India, and it is hoped that so far as the principal races are concerned the authors will in each case be members of those races. The scope of Mr. Yusuf Ali's paper is shown by the following passage:—"It is certain that an imperfect appreciation of the Indian Mohammedans is at the bottom of much of the misunderstanding that exists between them and the English, and between them and their Hindu fellow-subjects. Let us see if we can briefly review their past history, their present position, and their future prospects. In doing so let us hold in view not so much a narration of events as an appreciation of the moral factors which have made the Indian Mohammedans what they are, and which will doubtless operate in their attitude to future events." Although a minority of the population (they number 62½ millions) they are increasing faster than the Hindus, and Mr. Yusuf Ali holds that "if they have any consciousness of moral worth, their influence is, or might be, greater than can be measured by mere numbers." Their chief requirements were shown to be organisation and self-help.

The "Bhils of Western India" formed the subject of a picturesque paper by Captain E. Barnes, who, while serving in the "Bhil country" as an officer of the Political Department, made a careful study of the customs and habits of this interesting and attractive but backward and more or less wild race. Animistic in religion, they number, according to the last census, 1,200,000 souls, are averse from all forms of manual labour, but make good soldiers, and are gradually being brought under the influence not only of Hinduism and Mohammedanism but of Christianity. Captain Barnes expresses the opinion that with sympathetic treatment, and a careful regard to their home prejudices, they should eventually develop into a more settled community.

III.—Colonial Section.

The session opened in December, when, before a crowded and distinguished audience and under the presidency of Viscount Milner, the Hon. Sir Lewis Michell impressively discoursed on the aims and objects of the most ambitious of Mr. Cecil Rhodes's schemes, the Cape to Cairo Railway, as originally projected. The undertaking, Sir Lewis declared, is no unsubstantial dream but a reality, possibly in advance of its age but still a reality, and already in great part an accomplished fact. From Cairo or Alexandria southward to Assuan, a distance of 590 miles, the line, he announced, is constructed, and another 560 miles between Wady Halfa and Khartum, while a further extension of 410 miles to Usambara is projected. In the aggregate, the line from the north, completed or contemplated, is thus about 1,600 miles, and from the south rather more than 2,000 miles. Add to this the long Tanganyika waterway, and it will be seen that the great enterprise is already far advanced. Sir Lewis expressed confidence in the ultimate completion of Mr. Rhodes's splendid idea, and the Chairman was equally sanguine though he admitted that there "might be some delay, even considerable delay," in joining up the two ends of the line. But, he added, long before those two ends were joined, the existing portions (and he was speaking more especially of the South

African portion) would have fully justified all the great efforts which had been made to create them. Among those who took part in the discussion were Sir David Gill and Sir Douglas Fox.

Mr. George Wilson, C.B., Deputy-Commissioner of Uganda, read a reasoned and elaborate paper on the wonderful progress, moral and material, made by that Protectorate since Sir Frederick Lugard, rather less than seven years ago, received orders to proceed to the country and make a treaty with its inhabitants preparatory to the establishment of British control. Sir Fredérick Lugard, who presided over the meeting, delivered a notable speech, in which he claimed that the advance made in Uganda since his time is a proof of the ability of our race to meet what he thinks is the great question of the twentieth century, namely, the development of the tropics not only for the advantage of the native inhabitants but for supplying the increasing demands of European manufacturers for raw materials. Both Mr. Wilson and Sir F. Lugard bore ungrudging testimony to the "enormous work," as the latter called it, performed by the Mission Agencies, especially in regard to education, and Bishop Tucker, who also took part in the discussion, mentioned that he was actually looking forward to the establishment in the not distant future of a University in Uganda.

Under the title of "British Malaya," Sir William Hood Treacher read an excellent paper on a most interesting but not sufficiently well known part of the Empire, the countries enumerated in his survey comprising roughly an area of 351,600 square miles, and containing a population of some 12½ millions. Our marked success in governing British Malaya and the notable absence of discontent are attributed by the author chiefly to the sympathetic attitude of European officials towards the natives and to a generous expenditure on public works, roads and railways. The value of the paper was enhanced by the inclusion of some exhaustive ethnological notes by Mr. Walter W. Skeat, and by a useful description of the geological features of the Malay Peninsula from the pen of Mr. John Fordyce Balfour.

At the concluding meeting the Hon. John Winthrop Hackett addressed the Section on "Social and Economic Conditions in Australia," mentioning, amongst other interesting facts, that the Australian Commonwealth comprises more than 35 per cent. of the territory constituting the British Empire, and that with 97 per cent. of its inhabitants of English, Scotch and Irish descent it is "the most purely British portion of the Empire outside the Motherland." The Hon. Alfred Deakin presided, and made an excellent speech touching on the future of Australia. The Hon. W. M. Hughes, one of the leaders of the Australian Labour Party and an ex-Minister, also contributed to the discussion.

IV.—Applied Art Section.

The first meeting of the Section was held on December 18, when an instructive paper on "Basket Making" was read by Mr. Thomas Okey, who (himself a practical basket maker) was able to describe fully the technical points connected with one of the oldest of the arts. So little have these changed that the same "strokes" found in the oldest baskets discovered in the ancient Egyptian tombs are in use at the present time.

At the next meeting, on January 29, Mr. William Dale read an interesting paper on "The Artistic Treatment of the Exterior of the Pianoforte," in which he described some of the most remarkable examples of ornamented harpsichords and pianos, paying special attention to the beautiful modern instruments designed by Sir Lawrence Alma Tadema, R.A., Sir Edward Burne Jones, and the Chairman (Mr. T. G. Jackson, R.A.). Mr. Dale pointed out that improvements might be made in the form and decoration of the ordinary upright pianoforte without any great increase in its price. In the discussion attention was directed to the sound principle that the form of the case, however altered, should always follow the main lines of the instrument.

Dr. A. P. Laurie's important paper read at the third meeting—"Oils, Varnishes, and Mediums, used in the Painting of Pictures," was a complement to Prof. J. M. Thomson's paper on "Artists' Pigments," read last session. The author described his original experiments on this subject, and illustrated his paper with a valuable series of microphotographs. Sir Luke Fildes, R.A., presided at the meeting, and in the discussion the hope was expressed by the artists present that the further experiments on which Dr. Laurie was engaged would throw more light on the actual cause of the cracking of pictures.

Mr. A. Romney Green's paper on "Joinery and Furniture Making," read on April 16, contained a history of the art of joinery and a demonstration of the superiority of the older furniture by reason of the use in its construc-

tion of simpler tools than those afterwards introduced. The author drew special attention to the importance of the proper cutting of timber for the production of sound planks. The paper was illustrated by examples of old furniture from the Victoria and Albert Museum, lent by the Board of Education.

Mr. William Burton's paper on "Lustre Pottery" consisted of a brilliant exposition of the history of the changes in character of lustre from its origin, and the advances which had been made in the manufacture, especially in the case of the beautiful ware with its remarkable iridescence now made by Pilkington's Tile and Pottery Company. A singularly fine collection of historical and modern pieces from the Victoria and Albert Museum, and many other contributors, was exhibited.

At the last meeting of the session, on May 28, Mr. Sherard Cowper-Coles read an interesting paper on "Sheffield Plate and Electro-Plate," in which he traced the history of plating in metal from its practice before the introduction of Sheffield plate, which itself has been superseded by electro-plate. The Chairman (Sir John Edward Bingham), from his great experience of the subject, was able to supplement the information given in the paper, and an important discussion was the result.

V.—Cantor Lectures.

The first of the courses of Cantor Lectures during the present session was on "Artificial Fertilisers," by Mr. A. D. Hall, the Director of the Rothamsted Experimental Station under the Lawes Agricultural Trust. Mr. Hall's course was of an extremely valuable character and was well attended, though the subject is suited rather for a country than for a London audience. His first lecture was devoted to the consideration of the nutrition of the plant itself, and in it he showed that practically all the elements required for plant life were nitrogen, phosphoric acid, potash, lime, and magnesia, the first three being much the most important. The remaining four lectures of the course were consequently devoted to these three materials—two to nitrogen, one to phosphates, and the last to potash. In the two devoted to nitrogen, the first dealt mainly with the fixation of nitrogen and its supply to the plant; the second with the sources and character of nitrogenous manures. Up to the present time the source of supply of nitrogen has practically been found in the Chilian deposits of nitrate of soda. Attention has lately been drawn by Sir William Crookes, amongst others, to the question of the supply of nitrogen to plants after the Chilian and other supplementary deposits have been exhausted, and attempts, as is well known, have lately been made to obtain the nitrogen of the atmosphere in a form suitable for the manufacture of manures, and at a cost which would enable the artificial product to compete with the natural one. There are two methods of bringing the free natural gas into combination—the first by causing it to combine with oxygen to form nitric acid, and eventually nitrate of calcium; the second by causing it to combine with such a material as calcium carbide to produce calcium cyanamide, which will decompose under the action of water and yield its nitrogen as ammonia. This method is now being carried out on a commercial scale, and with considerable success. The production of nitrate of lime is also now running on a commercial scale, and, so far as the use of the manure goes, with perfect success. Mr. Hall found that chemically prepared nitrate of lime gave practically equivalent results when tested on a plot at Rothamsted to those obtained with a nitrate of soda crop alongside. The various phosphatic fertilisers were dealt with in the fourth lecture, natural phosphates, superphosphate from mineral phosphates, basic slag, resulting from the Thomas-Gilchrist basic process of steel making, &c. Potassic fertilisers formed the special subject of the fifth lecture, in concluding which Mr. Hall gave some useful advice to farmers as to the use of artificial fertilisers. He maintained that if the manure now used were more carefully bought, and more skilfully adjusted to soil and crop, the greater profit would justify an increased purchase of such materials, and a larger fertiliser bill on the part of the farmer.

The second course of lectures was by Professor J. W. Gregory, on "Gold Mining and Gold Production." The general object of the course was to afford the numerous class of people who are now interested, principally for financial reasons, in gold mining, but have no special knowledge of the subject, an opportunity of acquiring such information. The lectures, therefore, were of a popular rather than of a technical character, although there was much in them likely to be of use even to persons technically employed in gold mining. The first lecture dealt principally with alluvial gold mining, now to so large an extent a thing of the past. The second lecture treated of

lode mining, that is to say what is now generally known as gold mining. The chief goldfields of the world were referred to, and their structure described. The production of the gold, the crushing of the ore, and the extraction of the metal itself, formed the subject of the third lecture.

In the third course of the Session, Mr. F. Hamilton Jackson dealt with "Romanesque Ornament," and to this subject he devoted three lectures. The course was in fact a comprehensive treatment of a large and difficult subject. The lectures were illustrated by a beautiful and original series of lantern slides of specimens of ornament taken from buildings in all parts of Europe. The author described the cloister as the cradle of Romanesque, and referred to the universality of the appearance of similar designs in the various arts of architecture, miniature painting, textiles, ivory carving, &c. He laid special stress on the Oriental influence exerted on ornament in France and Italy. These lectures, as containing original examples of a great variety of Romanesque ornament, will help students to a clearer understanding of some of the difficulties presented in the history of this subject.

The last course of lectures was by Professor Herbert Jackson on the subject of "Detergents and Bleaching Agents used in Laundry Work." This important subject, though it certainly deals with a London industry of very considerable extent, has never before been made the subject of a course of Cantor lectures. Of the three lectures of the course, the first was devoted mainly to water and soap. The softening of water for laundry work was referred to, and easy methods were described for examining the value of soaps. The second lecture was devoted to bleaching agents, their composition, methods of application, value, &c. The third lecture was perhaps the most important, as it dealt with the whole question of washing fabrics, and their destruction by some of the methods used in modern laundry work. On the whole, Professor Jackson attributed the injury to fabrics now so much complained of rather to alterations in the fabrics themselves than to the use of improper agents for washing.

VI.—Juvenile Lectures.

The usual short course of Christmas lectures intended for a juvenile audience was delivered this year by Mr. Bennett H. Brough, the Secretary of the Iron and Steel Institute, who took for his subject "Perils and Adventures Underground."

After a brief sketch of the amount and importance of mining in every country of the world, and especially in great Britain, Mr. Brough passed on to a consideration of the dangers with which miners had to contend in every period. The old miner did not recognise the source of his dangers, and attributed them to various malignant influences But the modern miner, in spite of the advance of science, and the knowledge which had been gained, had to contend with the same difficulties, and on a larger scale. What these dangers were—fires, explosions, falls of roof, accidents in haulage operations and in machinery, inundations, and fire-damp—were all described, and the various methods which had been devised for minimising them, securing safety to the miner, and rescuing him after a catastrophe had happened.

VII.—Albert Medal.

The Council of the Society, with the approval of His Royal Highness the President, the Prince of Wales, have awarded the Albert Medal for the current year to the Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E., "In recognition of his preëminent public services in Egypt, where he has imparted security to the relations of this country with the East, has established justice, restored order and prosperity, and, by the initiation of great works, has opened up new fields for enterprise."

Lord Cromer more than any other man, has opened up Egypt and the Sudan to arts, industries, and commerce. For architects, engineers, and merchants, he has secured a wide and widening field. Lancashire spinners owe him a practically new source of supply of cotton, and manufacturers and users of India rubber will soon have to thank him for additional supplies of that article.

To him commerce owes the new facilities for discharging and loading cargoes at Alexandria, which are making that place one of the finest ports, if not the finest port, in the Mediterranean. It also owes to him an improved lighthouse service.

He did more than any one to bring about penny postage between this country and Egypt and the Sudan, and he helped to get the charge for telegrams reduced to a shilling.

The irrigation works, which his management of affairs has made possible, are converting deserts into fields and gardens, and

promise, in a few years, to afford means of living to large populations who are sure to make demands on industries and commerce, if not on arts.

But, above all, he has preserved to this country her connection with India and Australia, and her commerce with the Far East, by way of the Mediterranean, which must still remain the highway, however great may be the development of an alternative western route by way of Canada and the Pacific.

VIII.—MEDALS.

The Council have awarded the Society's Silver Medal to the following readers of Papers during the Session 1906-7 :—

At the Ordinary Meetings :—

To Mr. JOHN WILLIAM GORDON, for his paper on "Patent Law Reform."

To COLONEL SIR CHARLES M. WATSON, K.C.M.G., C.B., for his paper on "Some Objections to the Compulsory Introduction of the Metric System."

To Mr. ALBERT E. HUMPHRIES, for his paper on "Modern Developments of Flour-Milling."

To M. PHILIPPE BUNAU-VARILLA, for his paper on "The Panama Canal—the 'Lock Canal' type and the 'Straits of Panama' type."

To Mr. ARTHUR E. MORTON, for his paper on "Modern Type-writers and Accessories."

To Mr. NOEL HEATON, B.Sc., for his paper on "Mediæval Stained Glass, its Production and Decay."

To Mr. HERBERT WRIGHT, for his paper on "Rubber Cultivation in the British Empire."

To Mr. ALFRED EDWARD CAREY, M.Inst.C.E., for his paper on "The Protection of Sea Shores from Erosion."

In the Indian Section :—

To Mr. A. YUSUF-ALI, M.A., LL.M., Cantab., I.C.S., for his paper on "The Indian Mohammedans: their Past, Present, and Future."

To CAPTAIN E. BARNES, for his paper on "The Bhils of Western India."

To SIR FREDERIC S. P. LELY, K.C.I.E., C.S.I., for his paper on "The Practical Side of Famine in India."

To Mr. LAURENCE ROBERTSON, I.C.S., for his paper on "Irrigation Colonies in India."

In the Colonial Section :—

To Mr. GEORGE WILSON, C.B., for his paper on "The Progress of the Uganda Protectorate."

To HON. JOHN WINTHROP HACKETT, LL.D., for his paper on "Social and Economic Conditions in Australia."

In the Applied Art Section :—

To Mr. THOMAS OKEY, for his paper on "Basket Making."

To Mr. WILLIAM DALE, F.S.A., for his paper on "Artistic Treatment of the Exterior of the Pianoforte."

Of recent years it has been the practice that no medal should be awarded to readers of papers who had previously received medals from the Society. Acting on this rule the Council were precluded from considering the following papers :—In the Ordinary Meetings the paper by Major B. F. S. Baden-Powell on "Aerial Navigation." In the Indian Section, the paper by Sir Edward Charles Buck, K.C.S.I., LL.D., on "The Applicability to India of the Italian Methods of Utilizing Silt." In the Applied Art Section, the paper by Principal Arthur P. Laurie, M.A., D.Sc., F.R.S.E., on "Oils, Varnishes and Mediums used in the Painting of Pictures," and that by Mr. William Burton on "Lustre Pottery."

The Council, however, desire to express their high appreciation of these papers by thanking their authors for them.

The Council have always felt themselves precluded from awarding medals to members of their own body, and they, therefore, could not offer one to Sir William Hood Treacher, K.C.M.G., M.A., for his paper on "British Malaya." But they had much pleasure in recording their sense of the value of the paper by passing a special vote of thanks to its author.

IX.—INDUSTRIAL HYGIENE.

In February last the Council announced the offer, under the terms of the Benjamin Shaw Trust, of a Gold Medal, or a prize of £20, for improvements in industrial hygiene.* The Medal, under the conditions laid down by the donor, who died in 1877, is to be given, "For any discovery, invention, or newly-devised method for obviating or materially diminishing any risk to life, limb, or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means." Intending competitors are invited to send in descriptions of their inventions not later than the 31st December next. The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the judges nothing deserving the full award is sent in.

On several occasions when the prize has been offered, it has not been awarded, in consequence of the judges being unable to recom-

* See *Journal*, vol. lv., p. 323, Feb. 8, 1907.

mend any invention deserving it. The fund, consequently, has accumulated, and the Council now propose to devote the surplus to the provision of a course of lectures on "Industrial Hygiene," to be delivered some time next session. As soon as the necessary arrangements have been completed, particulars will be given in the *Journal*. The Council feel sure that this proposal would be in accordance with the wishes of the donor, since in 1876 he gave the Society a sum of £50 to cover the expenses of a course of lectures on "Unhealthy Trades," which were delivered by Dr. (afterwards Sir) Benjamin Richardson in that year.*

X.—Mulready Prize.

After the death of Mulready, in 1863, a fund was formed to establish a memorial to him. Sir Henry Cole was treasurer of this fund. The greater part of it was expended in erecting a monument over Mulready's grave in Kensal-green Cemetery. The balance, £109, was presented to the Society of Arts with the view of a Mulready Medal being presented occasionally to the student who should exhibit the best drawing from the nude at the annual examinations of the Education Department.

The Medal has been awarded on several occasions, the last occasion being in 1903. It is proposed to offer it again for competition amongst students of Schools of Art in the United Kingdom, at the annual competition to be held next year.

A gold medal, or a prize of £20, will therefore be offered to the student who obtains the highest awards in the following subjects:—

(*a*.) A finished drawing of imperial size from the nude living model.

(*b*.) A set of time studies on a small scale, from the nude living model, executed in a short time, of varied shortly sustained poses.

(*c*.) A set of studies of hands and feet from the living model.

(*d*.) Drawing from the life, including memory life drawing done at the Examination in May, 1908.†

XI.—Stock Prize.

In 1871 John Stock left £100 Consols to the Society, with the condition that the interest should be applied for the promotion of drawing, sculpture, and architecture. From time to time, as the accumulated funds permitted, prizes have been awarded under the Trust. In 1893 and again in 1897 prizes were offered to students in Schools of Art for architectural designs. A Gold Medal, or a prize of £20, is now offered* for competition among the students of the Schools of Art at the annual competition of 1908. The prize is offered for the best original design for an architectural decoration (to be carried out in painting, stucco, or any other process), for the side of a room or a hall, a ceiling, the apse or side of the chancel of a church, or any suitable part of the interior of a building.

XII.—Owen Jones Prizes.

After the death, in 1874, of Owen Jones, a committee was formed to collect subscriptions for the purpose of founding a memorial. The money thus obtained was partly expended in erecting a monument over his grave in Kensal Green, and the balance (a sum of £400) was presented to the Council of the Society of Arts upon condition of their expending the interest thereof in prizes to "Students of the Schools of Art who, in actual competition, produce the best designs for Household Furniture, Carpets, Wall-papers and Hangings, Damask, Chintzes, &c., regulated by the principles laid down by Owen Jones." The prizes have now been awarded annually since the year 1878 on the results of the annual competition of the Board of Education.

Six prizes were awarded this session, each prize consisting, in accordance with the regulations laid down for the administration of the Trust, of a bound copy of Owen Jones's "Principles of Design," and a Bronze Medal.

The list of the successful candidates has already appeared in the *Journal*.†

The next award will be made this summer, on the result of the present year's examinations. Six prizes have again been offered for competition.

XIII.—North London Exhibition Trust.

In 1865 the Committee of the North London Working Classes and Industrial Exhibition (1864) presented to the Society of Arts a sum of £157, the balance of the surplus from that exhibition, with a view to the award annually of prizes for the best specimens of skilled workmanship exhibited at the Art Workmanship Competitions of the Society of Arts. The Art

* See *Journal*, vol. xxiv., p. 116, Jan. 7. 1876.

† Further particulars of the conditions of the award will be found in the *Journal* for April 12, 1907. vol. lv. p. 575.

* Particulars of the offer will be found in the *Journal* for April 12, 1907, vol. lv, p. 575.

† See *Journal* for Sept. 14, 1906, vol. liv., p. 989.

Workmanship Competitions were discontinued after 1870, but since that date various prizes have been awarded under this Trust. Prizes were offered to the students of the Artistic Crafts Department of the Northampton Institute, Clerkenwell, in 1903, and have been continued annually to the present time. The results of the award for last year were announced in the *Journal* last November.* The offer has been renewed for the current year, but, as the accumulated funds are now nearly exhausted, notice has been given to the Governing Body of the Institute that after the present year the arrangement will have to be reconsidered.

XIV.—Fothergill Trust.

The Council have had their attention drawn to the need which exists for some rescue apparatus which would enable a succouring party to reach men cut off—in case of mining accidents—by irrespirable gases, or suffocated by them. Many such appliances exist, but it does not appear to have been decided which of them are the best, or even which are of practical use.

Under these circumstances they believe that a useful purpose would be served by the offer of a prize for the best life-saving apparatus for use in noxious atmospheres, and they have therefore determined to offer under the Fothergill Trust, a Gold Medal, or a prize of £20, for the best portable apparatus or appliance for enabling men to undertake rescue work in mines or other places where the air is noxious. It is intended that the apparatus sent in shall be submitted to practical trials and tests. The time and conditions of these will be announced later on.

Inventors intending to compete have been invited to send descriptions of their inventions not later than 31st March, 1908. Such specimens must be accompanied by full descriptions, and in cases in which the apparatus has been put into actual use, the experience of such use should be given. Competitors intending to patent their inventions should be careful to obtain protection, as the Council of the Society cannot undertake any responsibility as regards the secrecy of the whole, or of any part, of an invention submitted to them.

The prize will be awarded under the usual conditions on the report of judges appointed by the Council.† The competition is not limited to British subjects.

* See *Journal*, vol. lv., p. 215, November 30, 1906.

† Further details were given in last week's *Journal*, p. 802, vol. lv., June 21, 1907.

Dr. Anthony Fothergill died in London in 1813. He was an M.D. of Edinburgh, and after studying medicine at Leyden and Paris he settled as a physician in Northampton. He also practised in London and afterwards in Bath, where, according to the Dictionary of National Biography, he acquired a large and lucrative practice. In 1803 he retired from active life and went to Philadelphia. He returned to England the year before his death in 1812. He left a considerable fortune, most of which was distributed among various charitable and other institutions in London, Bath, and Philadelphia. The bequest to the Society was left to be dealt with at the Society's discretion in providing medals or premiums, but the subjects suggested for the consideration of the Society in the first instance all related to the protection of life from fire.

XV.—Aldred Lecture.

In 1868, Dr. Aldred left a sum of £100 to the Society of Arts, in order that the interest might provide annually a £5 prize for an essay on some scientific or literary subject. The actual amount of the bequest (£90) was invested in Reduced Three per Cents—£97 16s. 6d. The interest on this was obviously insufficient to provide an annual prize of £5, and the Council consequently determined, in 1883, to allow the money to accumulate until there was sufficient to provide an annual sum of £5. By the year 1902, the accumulation had become sufficient for the purpose, and at the present time there is an available surplus.

Having regard to the unsatisfactory results generally obtained by the offer of prizes for Essays, the Council considered that the wisest course to pursue would be to invite some scientific or literary man of eminence to deliver a lecture before the Society on some subject upon which he was recognised as an authority. They are pleased to be able to say that Sir William Ramsay has undertaken to deliver during the autumn the first Aldred Lecture; the subject selected will be connected with Radio-active Phenomena. The Council hope that they may be able to continue the series of Aldred lectures either annually or biennially, as the funds may permit.

The testator, Dr. George Edward Aldred, died in 1868. He was elected a member of the Society in 1862. He served with Her Majesty's army in India, was an M.D. of Paris 1841, became a member of the Royal College of Surgeons in 1843, and was made a Fellow in 1859. At the time of his death he

was resident in London. He bequeathed nearly all his property amongst public charities, mostly medical.

XVI.—Prizes for Drawing.

Since 1889, the Council have annually placed at the disposal of the Royal Drawing Society, for competition among the candidates at its annual examination, 12 Bronze Medals, and these medals were awarded for drawings sent in by students to the exhibition held by the Drawing Society in April last.

XVII.—Examinations.

In former years it was the practice to include in the Annual Report a full report of the results of the Examinations. The number of candinates entering for the Society's examinations is now so large, and the additional work involved by the addition of the Advanced Stage so considerable, that this is not now possible. A separate supplementary report on the examination of 1906 was published in the *Journal* of October 12th last after the results of the three stages had all been issued, and it is proposed to follow the same plan for this year. It is hoped to publish the results of Stage III., Advanced, early next month; of Stage II., Intermediate, at the end of July; and of Stage I., Elementary, in August.

The total number of papers worked was 24,568, the number last year being 24,179. These were divided among the various Stages as follows: — Stage I., 8,951; Stage II., 10,802; Stage III., 4,815. The corresponding figures for 1906 were—Stage I., 8,536; Stage II., 10,738; Stage III., 4,905. It will be seen therefore that there was a slight increase in Stages I. and II., and a decrease in Stage III.

The Council do not contemplate any modifications in the system next year, as it seems to work with perfect smoothness and to give general satisfaction to all concerned.

At the request of the Army Council, the Council have arranged to hold a special annual Examination in Shorthand for soldiers. The first Examination was held on March 27th, at twenty-three centres in the United Kingdom, one in India, and two in South Africa. In the Advanced Stage (speed 140 and 120 words per minute), there were 8 candidates, of whom 3 obtained 2nd Class Certificates, and 5 failed. In the Intermediate Stage (100 and 80 words per minute) 32 candidates presented themselves, of whom 14 obtained 1st Class Certificates, 9 2nd Class Certificates, and 9 failed. A similar Examination has been arranged in Type-writing to commence next year.

XVIII.—Viva Voce Examinations in Modern Languages.

Up to the present date 10 examinations have been held this year in London, Guernsey, and Manchester. Arrangements have also been made for holding examinations at several other centres.

At these examinations 280 candidates presented themselves, of whom 209 passed (34 with distinction) and 71 failed. The languages taken up were French, German, and Spanish.

The results of previous years are as follows:—

Year.	Number Examined.	Passed	Failed.
1902	280	202	78
1903	456	324	132
1904	540	375	165
1905	681	502	179
1906	644	469	175

These examinations are held at any of the Society's centres where the necessary arrangements can be made. They are held at any date convenient to the local committee. The examination includes dictation, reading, and conversation, and the examination is so arranged as to test efficiency in a colloquial knowledge of the language, without laying too much stress on minute grammatical accuracy. Candidates who are reported upon as highly qualified by the examiners, receive a certificate of having passed with distinction.

The examiners are Mr. E. L. Naftel for French, Professor H. G. Atkins for German, Professor Ramirez for Spanish, and Mr. Luigi Ricci for Italian.

The numbers this year, when all the examinations are finished, are not likely to show any considerable increase on 1906.

XIX—Practical Examinations in Music, 1906.

The practical examinations in Music were not concluded last year until the 5th July, too late for the results to be included in the Report of the Council. They lasted for 13 days.

The examinations were conducted by Dr. Ernest Walker, M.A., and Mr. Burnham Horner.

The system of examination was the same as that for recent years. For instrumental music certain standards are given, and candidates are asked to select for themselves which of these standards they choose to be examined

in. The standards range from easy to very difficult music. For each standard a list of music is given for study, and from this list candidates select the pieces they will sing or play. Candidates are expected to play or sing the pieces which they have prepared, to play or sing a piece, or portion of a piece, at sight, and to play certain scales.

In all, 477 candidates entered, and of these 467 were examined, an increase of 49 as compared with the previous year. There were 394 passes and 73 failures.

The following were the subjects taken up:—Piano, singing, violin, violoncello, viola, and bassoon. 383 entered for the piano, 320 of whom passed; 57 entered for the violin, of whom 48 passed; 6 entered for the violoncello, all of whom passed; 18 entered for singing, of whom 17 passed; two entered and passed for the viola, and one for the bassoon. No medals were awarded.

XX.—Practical Examinations in Music, 1907.

The Practical Examinations for the present year have not yet been concluded. They commenced on Monday, June 24th. They will be finished on July 10th, after which a summary of the results will be given in the *Journal*. The work of the examination is being carried out by the same examiners as in the last six years. 462 candidates have entered for the present examinations, a decrease on last year of 15.

XXI.—Soane Museum.

Under the Act by which the affairs of the Soane Museum are regulated, the Society of Arts have to nominate one of the trustees. The office is held for five years, and the last election having been in 1902, it is necessary that the Society should exercise its power during the present year. The Council recommend for election Sir George Birdwood, who has acted for the previous ten years, having been elected in 1902, and again in 1907.

In 1833 Sir John Soane presented to the nation the house which he had built in Lincoln's-inn-fields, and in which he had placed his very valuable collections of pictures and objects of antiquarian interest together with his extensive library. At the same time he obtained an Act of Parliament by which the property was vested in Trustees—four appointed by himself, and five by the Corporation of London, the Royal Academy, the Royal Society, the Society of Antiquaries, and the Society of Arts—the four original nominated Trustees having the power to fill up by election vacancies in their number as they occurred. The authority of all the Trustees is the same, but the property is vested in the Life Trustees, and they only have the power of signing cheques. Sir John Soane also provided the funds necessary for the maintenance of the house as a Museum. He died on the 20th of January, 1837, and shortly afterwards the Museum was placed under the authority of the Trustees.

The following is a list of the Trustees appointed by the Society of Arts:—

1837 to 1843—H.R.H. the Duke of Sussex, President of the Society.
1844 to 1857—H.R.H. the Prince Consort, President of the Society.
1857 to 1864—Sir Charles Wentworth Dilke, Bart.
1865 to 1876—Samuel Redgrave.
1876 to 1882—Alan S. Cole, C.B.
1882 to 1896—Sir Benjamin Ward Richardson, M.D., F.R.S.
1897 to 1907—Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.

XXII.—Deterioration of Paper.

In 1898 a Committee of the Society of Arts reported on the question of the deterioration of paper. This report specified certain standards, in which an endeavour was made to maintain a technical ideal. It also called attention to the question of permanence in relation to documents of value, and more particularly books.

The report has certainly had some effect, if only in making known the opinions expressed by competent authorities, but the Society has been reminded afresh that a large proportion of books are still being produced on perishable papers. This is due more particularly to the growing popularity of photographic reproductions, and the necessity of adapting papers to the requirements of the "process" block, and the dominant demand for cheapness.

The chief offender is the imitation art paper, heavily loaded with clay, and calendered so as to produce surface at the expense of the substance of the paper.

These, and other questions, are once more pressed on the notice of the Society, and with the object of again drawing public attention to the question, the Council have re-appointed the Committee. They hope that its report when published may contribute to a sounder public opinion on this very important question.

XXIII.—Honorary Royal Members.

On the occasion of His Majesty the King of Norway's visit to this country in October last, the Council, under the provision of the By-law authorising them to elect every year a certain number of life members of the Society, elected His Majesty an honorary life member; and this month they were able to take a similar course when His Majesty the King of Denmark was in England. In both cases the election was made with the full approval of His Royal Highness the President, who communicated Their election to Their Majesties.

Besides these latest additions to the list, the list of honorary Royal members now includes the King of the Belgians (1876), the King of Greece (1906), the King of Portugal (1906), the King of Spain (1905), and the King of Sweden (1876).

XXIV.—Bicentenary of Linnæus.

At the end of May the Royal Swedish Academy of Sciences, Stockholm, and the University of Upsala, celebrated the Bicentenary of the birth of Linnæus. The Society of Arts was invited by both bodies to send a Delegate, and Professor Hjalmar Sjögren, Professor of Geology in the Mineralogical Department of the Riks Museum, Stockholm, was good enough to accede to the request of the Council that he would act as the Society's Representative on this occasion. Professor Sjögren is a life member of the Society, he having been elected in 1904. The Universities of Oxford and Cambridge, the Royal Society, the Linnean Society, and several other British Institutions were also represented.

XXV.—Conversazione.

The Society's annual Conversazione for 1906 was held on the 3rd July, at the gardens of the Royal Botanic Society. The arrangements were the same as of recent years and the attendance was above the average. This year's Conversazione will be at the same place on the 9th of next month. This is the seventh year in succession for which the gardens have been placed at the disposition of the Society of Arts. The Council trust that the coming Conversazione may be as popular and as successful as its predecessors, all of which appear to have been well appreciated by the members.

XXVI.—New Council.

On the Balloting List presented to the Members in accordance with the By-Laws, by the Council, there are six newly nominated Vice-Presidents, the number having been increased by the unexpected death of Sir Benjamin Baker. The other retiring Vice-Presidents are Sir Owen Tudor Burne, Mr. Lewis F. Day, Sir William Lee-Warner, the Earl of Onslow, and Sir Marcus Samuel. In their places the Council propose Sir Steuart Colvin Bayley and Sir Aston Webb—both of whom were Ordinary Members of Council last year—and Mr. Carmichael Thomas, who has acted most efficiently since 1902 as one of the Society's treasurers. They also propose Sir William Abney, who was Chairman of the Council from 1903 to 1905, and Colonel Holden, who served on the Council from 1904 to 1906. They have also nominated Sir William Thomas Lewis, who has not acted in any capacity on the Council before, but whose name will be well known to the members as one of our greatest authorities on matters connected with coal and coal mining.

As usual four Ordinary Members of Council retire, their names this year being Sir David Barr, Sir Steuart Colvin Bayley, Professor J. M. Thomson, and Sir Aston Webb. In their places the Council recommend Sir Walter Prideaux and Mr. Henry Hardinge Cunynghame—both of whom have rendered very active service to the Society in many ways, and have been on the Council before—Mr. Thomas Jewell Bennett, and Mr. Arthur Crozier Claudet. Mr. Bennett has long been a member of the Committee of the Indian Section, Mr. Claudet is a Past-President of the Institution of Mining and Metallurgy, and has been a member of the Society since 1888. To replace Mr. Carmichael Thomas as Treasurer, the Council propose Professor J. M. Thomson, who retires by seniority from the Council.

The balloting list also bears the name of Sir George Birdwood, who is nominated by the Council for re-election to the Soane Trusteeship, as mentioned in another portion of this report.

XXVII.—Obituary.

Compared with some recent years the losses by death among the members, which the Council have to deplore, are less numerous than usual. Sir Benjamin Baker, who died last month, had served on the Council at intervals since 1888, and took an active interest in the work of the Society. His personal loss was felt very greatly by many Members of the Council, who knew him well and esteemed him highly. General Michael,

who took a very active interest in the Indian Section, and in 1894 read a paper on Forestry, was elected a Member of the Council in 1890, and served on it for one year. Another former Member of Council who died during the past year was Mr. James Dredge, who served on its body from 1890 to 1893.

Mr. Herbert Mills Birdwood was a very valuable member of the Committee of the Indian Section. He read two papers before the Section, for one of which he received the Society's medal. Not long before his death he read, in the absence of its author, Captain Barnes's paper on "The Bhils of Western India." Another useful member of the Indian Section Committee was Mr. Lionel Ashburner. He was elected a member of the Society in 1892. Yet another well-known figure at the meetings of the Indian Section, and a constant attendant at the Committee meetings, was Mr. Martin Wood, who had been a member of the Society since 1881, and of the Indian Section Committee since 1890.

Mr. Allan Wyon, whose firm for many years produced the Society's medals, became a member of the Society in 1892, and seven years later he read an interesting paper on the Great Seals of England. Mr. Sebastian Davis, who joined the Society in 1882, was a very frequent attendant at the Society's meetings. He was one of the oldest members of the Royal Photographic Society, which he joined in 1857. Lord Leven, who died last August, became a member of the Society in 1903. Mr. C. D. Abel had been a member of the Society since 1886. In 1904 he read a paper on "The Patent Laws," for which he was awarded the Society's medal.

Three very distinguished Foreign Corresponding Members of the Society died during the past year—Sir Dietrich Brandis, who took part in many of the recent discussions on matters connected with Forestry, and the two illustrious chemists, one French and the other Russian, Professor Marcellin Berthelot, and Professor Mendeleef.

XXVIII.—Finance.

The annual statement of receipts and expenditure was published—in accordance with the usual practice—in the *Journal* last week. It shows the revenue and expenditure for the financial year ending May 31st last, the Assets and Liabilities of the Society, its Investments and the Trusts standing in its name.

The Chairman, in moving the adoption of the Report, said they were fully justified in saying that it was a very good one. The papers read during the past session had given great satisfaction, and several of them were eminently good. The papers and lectures had ranged over a very large field, and there was scarcely a subject of human interest which was not at some time or other brought before the Society. He noticed the applause with which the announcement of the award of the Albert Medal to Lord Cromer had been received, and thought all the members would agree that it could not have been bestowed more worthily. As was shown in the paragraph in the Report, the award was not at all outside the scope of the Society, and the Council were acting quite in accordance with its constitution in recognising the valuable work which Lord Cromer had done in Egypt. He also referred to the admirable character of the Juvenile Lectures this session, which he felt sure had proved exceedingly interesting to adults as well as to juveniles. He thought the Society was to be congratulated on the fact that Sir William Ramsay had promised to give the first Aldred Lecture next session. He also spoke of the loss which the Society had sustained by the death of Sir Benjamin Baker, who took a great interest in the work of the Society, and was an assiduous member of its Council. Another matter with which the Council were dealing, although it was not in the Report, was the question of additional accommodation, which was very badly needed for the development of the Society. They had hoped at the beginning of the year that it would have been possible to secure further space on their present site, but up to the present the negotiations had not borne fruit, and they were now, at the end of the year, no better off than they were at the beginning. The financial position of the Society, as would be seen from the balance-sheet, was most satisfactory.

Mr. William Whitaker, F.R.S., seconded the adoption of the Report. He congratulated the Society on the admirable manner in which the year's work of the Society was epitomised, and thought it was a great advantage to the Members to have before them a recapitulation of the papers read during the session. He could assure the Members that the Society was not the only one that needed fresh quarters, for the necessity of obtaining additional accommodation seemed to be chronic amongst all the societies with which he was connected. He thought the Society had been very well served during the past year, and that the papers and lectures had been of the highest class.

The adoption of the report was then agreed to.

The Chairman, in complimentary terms, moved a cordial vote of thanks to Sir Henry Trueman Wood (the Secretary), Mr. Henry B. Wheatley (the Assistant Secretary), Mr. S. Digby (the Secretary of the

Indian and Colonial Sections), and the other officers of the Society. He said that no one who attended the meetings and read the weekly *Journal* could fail to recognise how efficiently the work of the Society was done by its staff, and their thanks were especially due to Sir Henry Wood and his colleagues.

The SECRETARY returned thanks for this expression of confidence in himself and in the other officers of the Society.

The ballot having remained open for one hour, and the Scrutineers having reported, the CHAIRMAN declared that the following had been elected to fill the several offices. The names in *italics* are those of members who have not, during the past year, filled the office to which they have been elected.

PRESIDENT.

H.R.H. The Prince of Wales, K.G.

VICE-PRESIDENTS.

H.R.H. The Duke of Connaught and Strathearn, K.G.
Duke of Abercorn, K.G., C.B.
Sir William Abney, K.C.B., D.C.L., D.Sc., F.R.S.
The Lord Chief Justice, G.C.M.G.
Sir Steuart Colvin Bayley, K.C.S.I., C.I.E.
Sir James Blyth, Bart.
Sir William Crookes, D.Sc., F.R.S.
Lord Curzon of Kedleston, G.C.S.I., G.C.I.E.
Francis Elgar, LL.D., F.R.S.
Hon. Sir Charles W. Fremantle, K.C.B.
Robert Kaye Gray.
Sir Cnarles Augustus Hartley, K.C.M.G.
Colonel H. C. L. Holden, R.A., F.R.S.
Lord Kelvin, O.M., G.C.V.O., D.C.L., LL.D., F.R.S.
Sir William Lewis, Bart.
Sir Philip Magnus, M.P.
Sir Westby B. Perceval, K.C.M.G.
Sir William Henry Preece, K.C.B., F.R.S.
Sir Owen Roberts, M.A., D.C.L., F.S.A.
Alexander Siemens.
Carmichael Thomas.
Sir Aston Webb, R.A.
Sir John Wolfe-Barry, K.C.B., F.R.S.

ORDINARY MEMBERS OF COUNCIL.

Thomas Jewell Bennett, C I.E.
Sir William Bousfield, M.A., LL.D.
Michael Carteighe, F.O.S.
Arthur Crozier Claudet.
William Charles Knight Clowes, M.A.
Henry Hardinge Cunynghame, C.B.
Henry Graham Harris.
Sir John Cameron Lamb, C.B., C.M.G.
Hon. Richard Clere Parsons, M.A.
Sir Walter S. Prideaux.
Sir Boverton Redwood, D.Sc., F.R.S.E., F.C.S.
Sir William Hood Treacher, K.C.M.G.

TREASURERS.

Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.
Prof. John Millar Thomson, LL.D., F.R.S.

SECRETARY.

Sir Henry Trueman Wood, M.A.

SOANE TRUSTEE.

Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.

On the motion of the CHAIRMAN, a vote of thanks to the Scrutineers was carried unanimously.

The Hon. Sir CHARLES FREMANTLE, K.C.B., proposed a cordial vote of thanks to the Chairman for his services in presiding at the meeting, and also as Chairman of Council during the past year. He was glad to say they would have the benefit of the services of Sir Steuart Colvin Bayley as Chairman of Council for another year, which he considered would be a great advantage to the Society.

The motion was seconded by Sir BOVERTON REDWOOD, D.Sc., F.R.S.E., who said that their high anticipations of the manner in which the duties of the Chairmanship of the Council would be discharged by Sir Steuart had been fully realised. The motion having been carried unanimously,

The CHAIRMAN acknowledged the vote of thanks.

The meeting then adjourned.

THE MEXICAN ISTHMUS RAILWAY.

On January 1st last the Tehuantepec Railroad, which runs across Mexico, a distance of 189 miles, was opened, and the experience already gained in working affords data for opinion upon the probable commercial results of this great undertaking. The Isthmus of Tehuantepec lies between the parallels of latitude 16° and 18° North, and the meridian of longitude 94° and 96° West. The Coatzacoalcos River, which rises at the foothills of the Sierra Madre, empties into the Gulf of Mexico, and at its mouth a natural harbour is formed, which is obstructed by a bar. On the Pacific coast, at Salina Cruz, there is no natural shelter—nothing but an open ocean roadstead. The Tehuantepec Railway joins these two points. As the bird flies, it is about 125 miles across the isthmus from ocean to ocean, but by the route which the railway is compelled to follow the distance is 190 miles. With the exception of the Panama route, it is the shortest trans-continental route. From the earliest

times its advantages as a line of communication between the two oceans have appealed to travellers and explorers. Hernan Cortes predicted that it would become the highway of the world's trans-continental commerce, and Humboldt described the isthmus as "the bridge of the world's commerce." The first actual steps for constructing some line of communication across the isthmus dates back nearly half a century. Concessions were granted, and in due course forfeited owing to the inability of the concessionaires to fulfil their obligations. In 1882 the Mexican Government determined to build the railway themselves, but the contract entered into for the work was rescinded when about 67 miles of the road had been completed. In 1888 a loan of £2,700,000 was raised for the purpose of carrying out the work which was given to Colonel McMurdo, who undertook to finish the road in thirty months, but died in 1890. In the beginning of 1892 new contractors undertook to complete the line in fifteen months, but the contract was soon afterwards cancelled. In 1893 fresh contractors undertook to complete by September, 1894, and the railroad was actually completed in that year, but no sooner was that done than defects in construction, as well as want of suitable harbour facilities on both the Gulf and Pacific coasts, made it necessary to begin work over again. The Mexican Government then entered into negotiations with the firm of which Sir Weetman Pearson is the head. The result was an agreement under which Messrs. S. Pearson and Son not only undertook to construct the railway but also the ports at Salina Cruz and Coatzacoalcos. The work both on the railway and at the ports was carried out with characteristic thoroughness, and, as has been said, the railway was opened on January 1 last.

The difficulties in the way of construction, both on land and at sea, were great. The heavy rainfall during the rainy season, the exuberant vegetation and other tropical conditions, the scarcity of labour caused principally by the fears of yellow fever, were serious obstacles, but they were overcome, and the railroad is now in excellent structural condition, with a good road built of rock ballast, and new steel bridges, that across the Jaltepec river being of six spans, 560 feet in length, whilst the Chivela pass is entered and crossed at a height of 735 feet above sea level. The equipment of the road is of the most modern description. The gauge is of the standard one of 4 feet 8½ inches; the numerous bridges are of steel with solid masonry abutments; culverts of adequate capacity have been put in wherever required in solid masonry; nearly the entire road is now laid with 80 lb. rails, and is ballasted with crushed rock and gravel; the ties are of creosoted pine, native hardwood, and Californian redwood, and are provided with heavy steel tie-plates. The route will at first be worked with a single track, and it is calculated that ten freight trains, carrying 300 tons net, can be despatched in each direction every 24 hours. It is claimed that freight can be transferred across the isthmus within thirty hours after the vessel enters the harbour at the other terminus, and the company promise a freight train service of 12 hours from ocean to ocean. If, however, the movement of freight proves as great as is expected, the line will soon have to be double tracked. All the locomotives burn oil fuel, at present imported from Texas in tank-steamers, and unloaded into three large storage tanks at Coatzacoalcos, each with a capacity of 6,000 tons. Soon, however, Messrs. Pearson and Sons' oil fields at San Christobel, on the Coochapa, will be in a position to supply oil. The consumption of oil fuel in the locomotives has a great advantage for travellers by the line in the freedom from smoke and coal dust, whilst an ingenious device for sprinkling the road bed with crude oil, heated to 210° Fahr., for destroying the roots of plants, and so preventing vegetation from overgrowing the track, lays the dust, and adds to the comfort of travelling in a hot climate.

The two terminal ports are still far from being completed, though the works at both ends are sufficiently advanced to admit of the entrance of large ships, and to make possible the speedy handling of freight. At Coatzacoalcos little remains to be done beyond deeper dredging of the channel on the bar, and the building of further wharves and warehouses, but at Salina Cruz there is still much to be done in dredging out more space in the inner harbour, building wharves and warehouses, and finishing the dry docks. The work on the harbours is not expected to be completed until 1909. The harbour at Coatzacoalcos, as well as that at Salina Cruz will have a depth of 33 feet at low water. At Salina Cruz on the Pacific, the engineering problem was much more serious than in the Gulf. The "Northers," which sweep across the isthmus beat the surf out to sea, and, since there is no natural shelter, it was necessary to construct both an outer or refuge harbour, and an inner harbour with wharves or a dry dock. Enormous breakwaters have been built far out into the sea, ending in a depth of 70 feet, with the convex side turned seaward, form the outer harbour. The entrance to this harbour is 656 feet across. The east breakwater is five-eighths of a mile long. It extends out for 1,200 feet in a straight line from the shore, then bends for 825 feet in a curve with a radius of about 1,900 feet, and then continues in a straight line for about 1,235 feet. The West breakwater is about 1,900 feet long.

The geographical effects of the railway upon commerce must be great. Some of the saving in distance by the new route is shown by the following Table of distances given in nautical miles:—

	Viâ Tehuantepec. miles.	*Viâ* Panama. miles.
From New York to San Francisco	4,226	5,401
From New York to Yokohama	8,666	9,831

From New Orleans to San Francisco	3,091	..	4,700
From Liverpool to San Francisco	7,182	..	8,033
From Liverpool to Honolulu	8,511	..	9,263
,, ,, Acapulco	5,274	..	6,033
,, ,, Yokohama	11,478	..	12,500

The line will compete under advantageous conditions for traffic between European and American ports on the Atlantic on the one hand, and ports in the far East and Australasia and on the Pacific coast of the American continent on the other. This traffic is now moving by vessels round Cape Horn, or through the Straits of Magellan, or by the Suez Canal, or by land over the trans-continental lines of North America. The prospects of freight are already so large that the officials informed Mr. W. Max Müller, Secretary to His Majesty's Legation at Mexico (from whose report, Cd. 3284, the particulars of the railway given above have been taken), that they were afraid to properly advertise their route for fear of not being able to comply with the demands of the traffic. The average saving in distance by the Tehuantepec route over Panama to all places on the Atlantic coast of the United States and Europe is, estimated at 1,250 miles. The ordinary freight steamer makes about ten miles an hour, say 250 miles a day, requiring five days longer *viâ* Panama, assuming the time of crossing the two isthmuses to be the same. It will take a steamer about one day to pass through the Panama Canal and the freight about two days to pass over Tehuantepec from ship to ship, leaving four days to the advantage of Tehuantepec. The extra cost of four days to a steamer, say 2,000 dols., plus the canal tolls, would make a 5,000 ton cargo about 10,000 dols. *viâ* Panama. The cost *viâ* Tehuantepec would be less, and there would be the saving in time of four days, which is of moment in this age of rapid transportation. The geographical advantages of the Tehuantepec route are very considerable.

UNITED STATES PETROLEUM PRODUCTION.

The oil production of the United States comes from five great fields and a few scattered States. The division into fields is governed by the quality of oil produced and the geographical position. Most of the great fields include more than one State, and in one case a State enters into two fields; this is Ohio, which, in its eastern and southern portion, belongs to the Appalachian field, and in its western part to the Lima, Indiana, and Illinois field. The five great fields referred to are the following:—The Appalachian field, the Lima, Indiana and Illinois field, the Mid-Continent field, the Gulf field, and the California field. As regards the scattered States, small quantities of oil have been produced for a number of years from Wyoming, Colorado, and Michigan. There are indications of oil, but no actual production from a number of other States. Wyoming shows the greatest probability of developing an oil field of importance.

The Appalachian field is the pioneer oil producer of the United States. From its point of discovery on Oil Creek, in Western Pennsylvania, it has been extended in a general north-eastern and south-western direction, until it now takes in an area of fully 50,000 square miles, and includes the production from New York, Pennsylvania, Eastern and Southern Ohio, West Virginia, Tennessee, and Kentucky.

The Lima, Indiana and Illinois field commenced to produce oil in commercial quantities in 1885, near Findlay, in north-western Ohio. This territory has been expanded until it extends diagonally across the north-west corner of Ohio and into Indiana. During the year 1905 a production of considerable extent was developed in eastern Illinois, near the Indiana line. These different productions are all grouped into the Lima, Indiana and Illinois field, which includes the production from Western Ohio, Indiana, and Illinois.

The Mid-Continent field first successfully produced natural gas in commercial quantities in 1894, in Kansas, and although a small quantity of oil was found at or near that date, it was not until the year 1899, that this oilfield was thoroughly opened up. Since that time, prospecting has gone on rapidly, extending the development in a south-westerly direction into Oklahoma and Indian territory. The Mid-Continent field includes the oil territory in Missouri, Kansas, Oklahoma, and Indian Territory.

The Gulf-field includes in its production the oil from Texas and Louisiana. The prominence of this field commenced with the Lucas gusher at Spindle Top in 1901. Prior to this time there was, from Corsicana and other districts of Texas, a production of oil of entirely different qualities from that produced below the coastal plains of Texas and Louisiana. This difference in quality, would justify the separation of the Corsicana district into a distinct field, but as the oil from this district is only about one per cent. of the production of the Gulf-field, this separation is not made in the United States statistics of oil production.

The California field.—Petroleum has been known and used in a small way in California since 1856. In 1865, an oil excitement passed over the State, during which many wells were drilled, and some petroleum was found. The real opening up of California as a great petroleum field dates, however, from 1892, when a shallow well, near an asphaltum deposit, in the city of Los Angelos was drilled, and a small but steady production of petroleum was obtained.

According to a report of the United States Department of the Interior, the most important features in connection with the production of petroleum in the United States, for the year 1905, are as follows:—(1.) The production was greater by 17,636,620 barrels than in any previous year. (2.) The value of the production for the year 1905 was £3,546,000 less than for the year 1904. (3.) The production of petroleum in the United States has

more than doubled within the last six years, the increase being in the heavier grades of the fuel class, while the production of the lighter or illuminating oils has remained constant. (4.) During the year the development of the Mid-Continent field and the extension into Illinois of the Lima-Indiana field indicate a great increase in the future production of the lighter grades of oil. (5.) The production of the great Eastern fields shows indications of permanent decrease. (6.) The completion of the pipe line from Humboldt, Kansas to Whiting, Indiana, marks another step in the transportation of oil. During the year 1905 there were produced within the United States 134,717,580 barrels of petroleum. This is an increase over the production of the year 1900 of 71,097,051 barrels, or considerably more than any total yearly production up to 1902. The foregoing statement gives an idea of the magnitude of the increase in the oil business of the United States. It does not, however, give a true and clear understanding of the business at this time. A simple statement of the number of barrels of petroleum taken from the earth each year no longer shows the condition of the industry. The kind and quality of the oil produced must now be taken into consideration, to have a proper understanding of the relation of production to demand and consumption. Of the production of the year 1905, 70,474,078 barrels were from the Gulf and California fields. This is almost exactly the quantity by which the production of the year 1905 exceeds that of the year 1900. The petroleum of the Gulf and California fields is of the heavier variety, and has a residue of asphaltum. Oil of this quality, although capable of producing a small percentage of illuminating oil, has its principal value in its use as a fuel. It is the demand for this purpose which must be looked to for the consumption of the production of heavy oils. The advantages in the use of petroleum as a fuel are many, and its acceptance as such is sure to grow until the price arrives at a figure that will bring it into competition with other fuels. It is well established that a barrel of petroleum is equivalent in heat-producing effect to between one-fourth and one-third of a ton of coal; hence the value of fuel petroleum must finally adjust itself to the cost of one-fourth to one-third of a ton of coal at the point of consumption. Prior to the year 1904, the greater part of the lighter grades of petroleum that are especially adaptable to the manufacture of the illuminating oils, came from the Appalachian and the Lima-Indiana fields. For a number of years the combined production of the two fields has been remarkably constant. During the period comprised between the years 1894-1903 inclusive, it has averaged about 55,500,000 barrels a year. The consumption of illuminating oil from 1894 to 1903 slightly exceeded the production. The stock held by the large pipe-line companies, which were 33,772,923 barrels at the end of the year 1897, were reduced to 20,772,823 barrels at the end of the year 1903. During the year 1904 there was a consumption of 55,968,171 barrels, against a production of 63,855,710 barrels, and in 1905 a consumption of 60,875,677 barrels, against a production of 63,855,710 barrels. These two years caused an increase in the stocks held of 8,717,140 barrels. The value of the total production of petroleum in the United States in 1905 was £17,532,000, as compared with £21,078,000 in 1904, although the production of 1905 exceeded that of 1904 by 17,636,620 barrels. As regards the order of production of the petroleum-yielding States, California still maintains a position at the head. Its output during the year was over one-fourth of the total production of the whole country. Texas comes next, showing a production of one-fifth of the total production; and then follow Kansas, Indian Territory, and Oklahoma.

PATENTS, DESIGNS, AND TRADE MARKS.

A Parliamentary paper (164) has been issued containing the 24th report of the Comptroller-General of Patents, Designs, and Trade Marks, with appendixes, for the year 1906. The report states that the work of carrying on the official investigation required by section 1 of the Patents Act, 1902, has proceeded satisfactorily during the year. This investigation, so far from having a deterrent effect on inventors, as was anticipated by some who were opposed to it, has been accompanied by an immediate and substantial increase in the number of complete specifications filed at the Patent Office. The number of these specifications, which was 15,831 in 1903 and 15,925 in 1904, rose suddenly after the investigation began, on January 1, 1905, to 18,806 in that year and 18,228 in 1906. A considerable part of the increase in 1905 was attributable to the more expeditious filing of these specifications, necessitated by the shortening of the time allowed for this purpose from nine to six months. But no such explanation will account for the increase in 1906. It is difficult to account for it on any other assumption than that inventors generally have appreciated the benefits which the official search has conferred on them. The applications for patents received in 1906 numbered 30,002, as compared with 27,577 in 1905, an increase of 2,425, or 8 8 per cent. Of these applications 21,012 were accompanied by a provisional specification, and 8,990 by a complete specification. The total number of patents which expired during the year was 14,146, and the total number of new patents sealed was 14,707. Thus the number of existing patents was increased during the year by 561. The number of designs applied for during the year amounted to 21,262 exclusive of 739 "sets" of designs. In the previous year 23,262 single designs and 869 "sets" were applied for. The number of designs registered was 21,212. The number of applications made in 1906 for the registration of trade marks (including 153 applications made to the Cutlers' Company of Sheffield) was 11,414, as compared with 10,527 in 1905. The number of trade marks registered was 4,731.—*The Times.*

HOME INDUSTRIES.

The Railway Companies and Coal Carriage. —The railway companies have intimated that on and from the 1st of July next coal, coke, breeze, and patent fuel will be charged "on the Standard Imperial avoirdupois weight of 20 cwts. per ton net." For a decade past the railway companies have been practically carrying 20½ cwts. of coal for the rate authorised to be charged for 20 cwts., and it is hardly surprising that at a time when their coal bills show, or must shortly show, serious increase owing to enhanced prices, they seek to partially to recoup themselves as indicated. Naturally the coal companies object, and it remains to be seen what the Board of Trade and the Railway Commissioners will decide. The contemplated charge is equivalent to an increase of 2·44 per cent. in the rates, and on the coal trade of London will represent an addition of between 2d. and 3d. per ton, taking the average. On the face of it the railway companies would seem to be within their rights. The special allowance as to weight was given under the stress of competition, and where there is no binding undertaking to continue it may, one would suppose, be withdrawn at pleasure. But the theoretical right of railway companies to charge what rates they please provided they do not exceed the Parliamentary maximum rates would seem to conflict with the clause of the Railway and Canal Traffic Act of 1894, which throws upon the companies the onus of proving that any increase in rates as applied to a particular class of traffic is warranted by the circumstances of the case. The clause in question enacts that where a railway company has directly or indirectly increased any rate or charge then, "if complaint is made, it shall be for the company to prove that the increase of the rate is reasonable, and for that purpose it shall not be sufficient to show that the rate or charge is within any limit fixed by an Act of Parliament or by any Provisional Order confirmed by Act of Parliament."

A Shipbuilding Combine.—The interesting announcement is made that Messrs. Harland and Wolff, Limited, of Belfast, and Messrs. John Brown and Co., Limited, of Clydebank and Sheffield, have entered into a sort of semi-amalgamation. The capital of John Brown, Limited, now consists of £1,750,000 of 5 per cent. cumulative preference shares of £10 each, 1,160,000 ordinary shares with 15s. paid up, and 590,000 shares fully paid. In their report the directors say that "with a view of strengthening the shipbuilding connection of the company, we have arranged for the acquisition of an interest in the firm of Harland and Wolff, Limited, of Belfast," and that for this purpose, as well as for completing the purchase of a field of ironstone, and for building two blast furnaces at Frodingham, additional capital will be created. Harland and Wolff, it is understood, will take up the greater part of the new shares, and John Brown and Co. take shares in new capital to be created by Harland and Wolff. These two companies are the two largest shipbuilding companies in the world, and it is interesting to remember that whilst Harland and Wolff are intimately connected with the great American shipping combination which five years ago secured the control of the White Star and other lines, Messrs. John Brown and Co. built the *Lusitania* for the Cunard which, with her sister ship, the *Mauritania*, is intended, by the help of a large Government subsidy, to combat the American combination. At present, Messrs. Harland and Wolff have their hands very full, and, unaided, might find difficulty in building to time the nine very large and fast steamers the American company have ordered for the Atlantic trade. The pressure will be relieved by passing on some of the contracts to Clydebank, the division of contracts ensuring continuity of work at both yards. At their Sheffield works Messrs. John Brown and Co. turn out the heaviest known plates rolled, and their association with Messrs. Thomas Firth and Sons, Limited, give them the supply of most other structural steel for shipbuilding. The semi-combination of these two great shipbuilding organisations is the latest illustration of the present day tendency towards industrial combinations, a tendency not without its serious disadvantages from the national point of view.

Tin, Lead, Spelter.—A little more than a year ago tin was quoted at £213 per ton, being by much the highest price upon record. Since then it has fallen steadily, until at present it is under £180. But it is noteworthy that the stock of tin in London has now been reduced to 1,405 tons, a record figure. Th imports of tin in May were much lower than usu being 2,695 tons against 3,651 tons in 1906, a 3,783 tons in 1905. Also the imports of tin ore a much below those of last year. On the other han the value of lead continues to rise, and has brought near that of spelter. It has not so nearly appreciat since October, 1900, when virgin spelter was quot at £18 15s. for a few days, and lead at £18 7s. 6 Lead then declined in price until it dropped t £10 10s. per ton in December, 1901. From tha date until recently there was a difference of fron £7 to £12 per ton between the two metals. Thi difference has now been reduced to about £2 17s. 6d. and it is possible that it may disappear entirely. Th market for spelter is declining, and the rise in lea appears to be due to shortness of supply alone Spanish producers are said to have sold their pro duction ahead to a considerable extent, and littl increase is to be looked for from Australia.

The Iron Trade.—It has been recently stated with some persistency that the industrial "boom" in Germany shows signs of nearing the end, and that these are specially noticeable with respect to the iron trade. As the German position has a very direct and

important bearing upon industries in this country, a statement just issued by the German Steel Syndicate, and intended to counteract the reports of reaction, will be read with attention. According to this official communication, the orders on the books for unfinished products for delivery during the four months June to September amount to nearly $2\frac{1}{2}$ million tons. The syndicate estimate that they will be required to keep back about 10 per cent. of this for later delivery, leaving $2\frac{1}{4}$ million tons to be delivered by the end of September, whereas they have provided for an output by the members during that period of only 2,060,000 tons, and it will probably be impossible to deliver more than 1,950,000 tons. Many more orders could have been booked, the syndicate say, if it had been possible to quote anything like near delivery. The decline in exports is reported to continue, but this is entirely due to the inability of the works to satisfy the home demand. It is admitted that the orders for girders are 100,000 tons less than at the corresponding period last year, but this is said to be due to the position in the money market, and was foreseen by the syndicate over a year ago. On the other hand, orders are on the books for over 300,000 tons more railway-building material than last year. The decrease in the output from the works is attributed to the scarcity of coal and raw material, the diminished production of the workers individually, and the shortage of railway waggons. The syndicate consider the outlook excellent, and that it will probably remain so.

Fast Colours.—At a meeting of the directors of the Manchester Chamber of Commerce, held a few days ago, they had under discussion the tests for colours as regards fastness in dyeing and printing. The test for fastness recommended by the Chamber is: "Let two parts by weight of the neutral soap known as Marseilles soap be dissolved in 1,000 parts by weight of soft water; put in the fabric for fifteen minutes without rubbing at a temperature not to exceed 150 degrees Fahrenheit. Any colour that will resist this should be considered fast; the converse being of course implied." Mr. George Edward Wright, of Offerton, Stockport, writes as a dyer of many years experience, to deny the efficacy of the test. It reads to him rather as if it might be intended to hide the faults of the new colours than to be a test of their stability. He wants to know what is Marseilles soap as made to-day. There are, he says, twenty different qualities of the soap on the market. Then the fabric is to be immersed for fifteen minutes at a temperature of 150 degrees Fahrenheit. There are a whole host of new direct dyes that will stand this test splendidly, and it is about the only one they will stand. They will hardly stand one day's sunshine, and, according to the test set down, they must never go to the wash, for the ordinary English washerwoman, or the natives wherever these goods go, will (if they desire to clean the garment) subject it to a much more severe test."

Directors' Fees in Cotton Mills.—The question of directors' fees is a favourite subject of discussion in Oldham, where probably more working-men are interested in joint stock companies than in any other town of its size in the United Kingdom, and very exceptional interest is shown in the affairs of its many cotton companies. The general impression at Oldham seems to be that although modest as compared with the fees usually allowed to London directors, the remuneration of Oldham directors is too large. The average seems to have risen a good deal of late years. A generation ago the fees were usually very small, about £4 a quarter, but many Oldham companies to-day allow £50 a year to each director. In some cases the fees would seem to be even higher. For example, a few days ago an Oldham company passed a resolution to pay £100 per annum to each director as against £75 hitherto, but strong opposition to this increase having been evinced by leading shareholders, the directors decided not to act upon the vote. Much must depend upon the extent to which the duties of the office trench upon time. With some shareholders the objection is not so much to a substantial fee being paid to each of the directors as to the practice of one director sitting upon many boards.

Mining Royalties.—There is little present likelihood of Parliamentary interference with Mining Royalties, but from time to time the public are reminded that in some cases trade is rather seriously handicapped by a system less favourable to the producer than that followed in countries which are our most serious commercial rivals. The Royal Commission on Mining Royalties which sat some time ago estimated Mining Royalties to average about $5\frac{1}{4}$d. per ton of coal, and about 9d. per ton of iron ore in 1889, but the price of coal is now at least one-third higher than in 1889, and as royalties are in many cases based on "sliding scale" principle they probably now reach 8d. per ton of coal on the Royal Commission's calculation. A correspondent of the *Manchester Guardian* gives reasons for the conclusion that royalties of all kinds — lease - fees, "dead" rents, underground and surface way leaves, water leaves, air leaves, &c.—now amount to much more than 8d. per ton, and puts it at an average of 1s., and the tendency is said to be still upward. In Germany mining royalties are fixed by the State at 2 per cent. on the profits of the business; in Belgium the rate is $2\frac{1}{2}$ per cent. on profits, and in France 5 per cent. on profits. The State owns the minerals and grants the mining concessions. No profit no royalty. Assume that a German company makes 6s. per ton profit, it pays only about 1s. 4d. in royalty. More than any other country the United Kingdom is dependent upon manufactures, and chief among them are now iron and steel. An excessive tax on minerals in the way of royalty must necessarily handicap those who have to bear it.

OBITUARY.

ALEXANDER STEWART HERSCHEL, M.A., D.C.L., F.R.S.— Dr. Herschel, Hon. Professor of Physics and Experimental Philosophy at Durham College of Science, Newcastle-on-Tyne, died on the 18th inst. at his residence, the Observatory-house, Slough, where previously resided his distinguished grandfather (Sir William Herschel) and father (Sir John Herschel). He was the second son of Sir John Herschel, and was born at the Cape of Good Hope in 1836, when his father was engaged on his historical series of observations at the Cape. He wrote a large number of papers on Meteoric Astronomy and Meteorological subjects, which are registered in the Royal Society Catalogue of Scientific Papers. He was elected a Fellow of the Royal Society in 1884, a Fellow of the Royal Astronomical Society in 1867, and a Member of the Society of Arts in 1892.

SIR JOHN FREDERICK CREASE, K.C.B.—Major-General Sir John Crease, late Commandant Royal Marine Artillery, died at Guildford on the 21st inst. He was born in 1836, educated at Upper Canada College, Toronto, and entered the army in 1854. As a subaltern he served in the China war of 1857-61. In the Ashanti war of 1873 he was present at the action of Essaman, and his services there were mentioned in despatches, and were rewarded with the brevet of Major. He was the inventor of an anti-fouling composition for coating the bottoms of iron ships, largely used in the Royal Navy; of a system for the drainage of Portsmouth; and of a composition for raising smoke to cover an attack when smokeless powder is employed. Sir John Crease was elected a member of the Society of Arts in 1878, and in April, 1902, he read a paper on "Ceuta and Gibraltar," for which he received the Society's silver medal.

GENERAL NOTES.

ICELAND FISHERY.—Signs are not wanting, says Mr. Consul Walsh in his report on the trade of Dunkirk (Cd. 3283), to show that the Iceland cod line fishing is a declining industry in a great measure owing to the successful competition of steam trawlers. The number of sailing vessels leaving for these fisheries decreases yearly. The results of the catch by the 54 vessels that went out last year amounted to 2,321 tons of cod compared with 2,826 tons in 1905, and 119 tons of oil compared with 205 tons in 1905. For the current season a change has been made in the mode of payment of the crews, among whom 1s. per barrel of about 3 cwts. is divided, plus 2d. per tail of the codfish caught by each man. There has also been a reduction made in the advances given to the crews which in preceding years varied from 650 francs to 750 francs. This has now been reduced to 550 francs. It is hoped that this arrangement will act as an incentive to the crews, who under the previous system received before setting out practically all they could hope to gain during the

RUBBER IN FRENCH WEST AFRICA.—The French Government is turning its attention to the better administration of the rubber forests of French West Africa. On the whole the quality of the rubber produced continues to improve, and prices have risen all round. The rubber, however, from the Ivory Coast and the Casamance district is still inferior to that from the other colonies, and somewhat strict measures are to be taken to improve it. The shortage in the export of rubber is due to adulteration which has made Ivory Coast rubber to a certain extent unacceptable in Europe, and secondly, less rubber has been brought across the Gold Coast frontier from Ashanti to exchange for gunpowder at Aborisso. A special survey is being made of the chief rubber-producing districts, which will eventually be divided into three categories as follows:—(1) Unexploited districts. These consist only of a few regions in the Ivory Coast forests. (2) Districts which are exploited but have not been spoiled by excessive production and unscientific methods of collection. (3) Districts which have been spoiled for the above reasons. These latter are in the majority. When the survey and classification are complete the Governor General will, by decree, close the worst districts to rubber collection, so as to give the plants time to recuperate. A beginning will probably be made in 1908.

GERMAN TOYS.—In his report on the trade of the consular district of Leipzig just issued (Cd. 3283), Consul-General Baron Bernhard von Tauchnitz refers to the export value of toys, which for 1905 was 20,260,000 marks, thus taking the tenth place among the important German articles of export to the United Kingdom. Of all British colonies Australia remains the best buyer of German toys, taking goods to the value of 1,390,000 marks in 1905. Toys take the third place among the chief imports of New Zealand. The import into British India has again increased. The value for 1902 was 574,000 marks, for 1903 700,000 marks, for 1904 832,000 marks, and for 1905 852,000 marks, 1906 is expected to show a further increase. On the other hand the exports to South Africa fell from 677,000 marks in 1903, to 369,000 in 1905. A further decline is also discovered in the export to Canada, the value for 1904 and 1905 being 913,000 and 551,000 marks respectively. total value of the exports of German toys to the United Kingdom and her colonies for the year amounted to 24,000,000 marks, which represents about 35 per cent. of the total exports to all countries, which amounted to about 68,000,000 marks.

Journal of the Society of Arts.

No. 2,850. VOL. LV.

FRIDAY, JULY 5, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

CHAIRMANSHIP OF COUNCIL.

On Monday, 1st inst., at their first meeting the Council elected Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., as Chairman for the ensuing year.

COUNCIL.

At the meeting of the Council on Monday, 1st inst., Major-General Sir Owen Tudor Burne, G.C.I.E., K.C.S.I., was elected a Member of Council in place of Sir Walter S. Prideaux, who is unable to accept the office to which he was elected at the Annual General Meeting on the 26th ult.

CONVERSAZIONE.

The Society's Conversazione will be held, by arrangement with the Council of the Royal Botanic Society, in the gardens of that Society, Inner Circle, Regent's - park, on Tuesday evening, July 9th, from 9 to 12 p.m.

The central portion of the gardens only will be used. The Conservatory and the Club house will be open.

The reception, by Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Chairman, and the other members of the Council, will be held at the entrance to the Conservatory, near the Broadwalk, from 9 to 10 p.m.

The Victoria-house, containing the Giant Water Lily (Victoria Regia), and other interesting tropical plants, will be open to visitors, and will be specially illuminated for the occasion.

An Exhibition of Growing and Cut Roses and other Flowers will be arranged in a marquee in the grounds by Messrs. W. Paul and Sons, of Waltham-cross.

A Selection of Music will be performed by the String Band of the Royal Marine Light Infantry (Portsmouth Division) in the Conservatory, and by the Band of H.M. Coldstream Guards in the Gardens, commencing at 9 o'clock.

A "Watteau" Pastoral Play in three acts, entitled "La Marquise," will be performed in the Gardens by Mr. Patrick Kirwan's Idyllic Players, commencing at 9.30 p.m.

A Concert and Entertainment, under the direction of Mr. Patrick Kirwan, will be given in the Club-house at 9.45 and 10.45 p.m.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. These tickets have now been issued. In addition to this, a limited number of tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the conversazione. On that date the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

Further particulars as to the musical and other arrangements will be given in the Programmes, which will be distributed on the evening.

PRIZE FOR INDUSTRIAL HYGIENE.

The Council of the Society of Arts are prepared to award, under the terms of the Benjamin Shaw Trust, a Gold Medal, or a prize of £20.

The medal, under the conditions laid down by the testator, is to be given "For any discovery, invention, or newly-devised method for obviating or materially diminishing any risk to

life, limb, or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means."

Intending competitors should send in descriptions of their inventions not later than December 31st, 1907, to the Secretary of the Society of Arts, Adelphi, London, W.C.

Such descriptions may be sent in under the inventor's name, or under a motto, accompanied by a sealed envelope enclosing the name, as preferred.

The Judges will be appointed by the Council.

The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the Judges nothing deserving the full award is sent in.

LIQUOR TRAFFIC LEGISLATION OF THE UNITED STATES.

At a time when the Government is believed to be contemplating liquor traffic legislation, the report of Mr. R. C. Lindsay, Second Secretary to His Majesty's Embassy at Washington (Cd. 3284). upon the liquor traffic legislation of the United States, is a timely reminder of what has been done in America to restrict the excessive consumption of alcohol. Probably there is no question which has attracted greater attention in the United States, induces sharper controversy, or has led to more legislation. During the past three years the States have enacted 164 separate laws directly affecting the liquor traffic. Mr. Lindsay has found it difficult to supply information as to the practical working of these laws. This usually depends on the local authorities, and the effects of the same law may be different in adjoining counties. Such statistics as can be obtained furnish little basis for comparison without a thorough knowledge of local conditions. Especially so is it with figures which are often given of the numbers of arrests for drunkenness. The variations noticed may be due not so much to changes in the law as to changes in the personnel of the police, or in the policy of the saloons, with regard to intoxicated persons, or to the rise of some energetic civic reform association. At one time or another 17 States have had stringent prohibition. It is now only retained by three, and in those, says Mr. Lindsay, it cannot be looked upon as a success. Parts of prohibitory States have always been in open violation against the law. Drinking has never been impossible, the sale of liquor has always been profitable, and seldom disreputable in the eyes of the public. Violation of the law has been open and avowed. In Urban districts at any rate, it has not been found possible to find any sound ethical basis for the law, or to persuade the majority to regard its violation as immoral. Without the backing of public opinion no enforcement of prohibition has been obtained, except at the price of raising animosities between rival factions of such intensity as seriously to disturb the community. Juries have violated their oaths; judges have hesitated to impose statutory penalties; blackmail and corruption have been directly instituted, and the law in general brought into contempt. Persistent disregard of the liquor laws is supposed to encourage disobedience to other enactments, and an example is cited in Kansas, where the fact that an anti-gambling law is almost a dead letter, has been attributed to the lax enforcement of prohibition in the cities of the State.

Local option is now the most widely prevalent system in the United States, embodying as it does the thoroughly American principle of decentralisation and delegation of authority. The Constitution allows each State, if it chooses, to prohibit the sale of intoxicants; so the States allow each county, city, or town likewise to adopt prohibition if they wish. It is almost invariably found that the towns vote for license, and the country districts for prohibition. The three States which retain prohibition are almost entirely agricultural communities. It is impossible to say whether prohibition has actually diminished drinking, but it has certainly made it more difficult for the ordinary man to get a drink, and temptation has thus been removed from many. Ohio is the purest example of the tax system. Iowa, though theoretically a prohibition State, really follows the same policy, the payment of a tax, and compliance with a number of well-devised regulations, being made a bar to proceedings against a dealer for selling liquor. It is noteworthy that the question of compensation, so important in this country, scarcely exists in the United States. The temperance feeling is so strong there that the license to sell liquor is looked upon as a franchise belonging to the Government, and a privilege only granted as a favour to certain selected individuals. The license is never issued for a longer period than one year, and from this fact the logical conclusion is drawn that it may be withheld when it lapses without the Government incurring any liability to compensate its holder. At one blow, and with no more than a few weeks' warning of any kind, South Carolina revoked all licences and turned the liquor business into a Government monopoly, but no compensation was given. Neither in any of the States where laws have been passed with the avowed object of reducing the number of saloons, nor in those in which licenses are at any time liable to be terminated by local option, is any provision made to compensate the dealer.

Maine may be called the home of prohibition. In 1905 the so-called Sturges Commission set to work and in Portland everything in the way of saloons and bar-rooms was closed, the Sheriff even seizing the liquors in the City Agency, which had just been opened, and had to be shut up for a considerable period. The result has been to draw the liquor trade into the hands of "Pocket Peddlers," and the sailors, longshoremen, strangers, and so on can get nothing but

the most villainous sort of liquor. "Prohibition," writes Mr. Keating, "while it certainly restricts the sale of liquor, does not suppress it. While the poor, improvident, or stranger is compelled to seek the 'Pocket Peddler,' the average non-abstainer can get rather more than he wants at the numerous clubs, or else at his or his friends' homes; and if his wants are running low, a telephone order to a dealer in a neighbouring State will soon replenish his stock by the next train, or by express." Where the sentiment of the community is adverse to the prohibition, the traffic is carried on in defiance of the law. The liquor would be kept in one house and conducted through pipes to another, the spigots being cunningly concealed; or a secret door would open and disclose a well-filled glass, or a revolving closet would be contrived in a partition wall, the thirsty one would place in it a token and a coin, and when the closet had completed its revolution, he would find in their place the means of quenching his thirst. All this secret trade brought with it the usual means of combating it. Professional informers and searchers abounded, and were generally of the lowest class. Blackmail flourished, the security of private life was violated, the costs of prosecution increased, and their results diminished, witnesses perjured themselves, juries would refuse to convict in cases of overwhelming evidence of guilt, and respect for the law vanished. Such is the story of temperance legislation in Iowa. On the other hand, it is admitted that it wiped out completely 150 breweries, compelled one of the largest distilleries in the country to cease business, and diminished public drinking. Whether or not it increased private drinking to a considerable extent is a matter of doubt, as also the question whether the quality of the liquor generally drunk did not deteriorate. On the whole, says Mr. Lindsay, there is much legislative unrest in regard to the liquor traffic, and every State is constantly amending its laws on the subject, but there is a well-marked tendency throughout the country to do everything possible with the object of restricting the traffic as efficiently as possible by the least obnoxious means, and of diminishing the evils which it brings in its train.

SMALL HOLDINGS IN THE UNITED KINGDOM.*

The several inquiries into the small holdings question, while they have brought together a great deal of valuable information, have still left the data very incomplete whereon to determine the economic position of the small holding. At the present time there is difficulty even in ascertaining the number and size of small holdings in the United Kingdom, while information is still more imperfect as regards the cropping and stocking of these holdings, their expenditure and receipts, and the general economic strength and efficiency of the small holding in relation to the medium and the large-sized holdings. Viewed from the point of view of the national balance of population, and from the standpoint of general social economics, the case for small holdings has received a wide provisional acceptance. But there is not yet ripe conviction on the matter, and this cannot come until there has been a thorough examination and settlement of the agricultural economics of the question.

Before proceeding, it may be well for the purposes of discussion to recall the definition of a small holding and to exclude certain classes of small holdings from the present consideration. The Small Holdings Act of 1892 defines a small holding as "land which does exceed one acre, and either does not exceed 50 acres, or if exceeding 50 acres is of an annual value for the purpose of income tax not exceeding £50." The present Small Holdings and Allotments Bill for England defines a small holding as from 5 to 50 acres, and places allotments at from 1 to 5 acres—a desirable limitation in the definition of a small holding. But it is desirable, in view of the very wide range of the type of small holdings, to define the scope of the present discussion still more particularly. Accordingly, I do not consider here holdings, whether under or over five acres, existing under conditions of soil and situation whereby a very specialised culture, such as bulbs, flowers, fruit, and vegetables, is carried out on a highly intensive scale. These are types to which everyone interested in the development of small holdings must attach great importance. But the problem which I raise for discussion is the small farm holding with average land and average facilities as regards markets, on which the holder is earning his whole livelihood. What is the economic position and outlook of this type of holding? The question of the small economic farm holding, I venture to think, is the main small holding question. At present it affects a large class of the community, for, apart from new holdings of this order which may be brought into being, there are hundreds of thousands of such holdings existing in the United Kingdom. In this connection, therefore, I wish to consider the following points:—

(1.) The statistical evidence as to the number and size of small holdings in Great Britain and Ireland.

(2.) Certain changes in agricultural economic conditions affecting the small holding problem, especially (*a*) the shrinkage of the area of tillage, (*b*) the increase in agricultural imports, and (*c*) the changes in agricultural prices.

(3.) Conditions essential to the economic development of a small farm holding.

The author has drawn largely on Irish evidence and statistics, partly because they are more familiar to him, and partly because Ireland is pre-eminently a country of small holdings. These points are fully considered in the paper with the following results.

* Abstract of a paper by Mr. W. G. S. Adams, M.A., entitled "Some Considerations relating to the Position of the Small Holding in the United Kingdom," which was read before the Royal Statistical Society on 18th June.

1. *Size and Number of Holdings in the United Kingdom.*—In considering the number and size of holdings in the United Kingdom, it will be remembered that the statistics of the number and size of holdings in Great Britain deal only with the areas of cultivatable land, *i.e.*, the area under crops and under pasture, excluding rough and mountain grazing, whereas in the case of the statistics of the size and number of holdings in Ireland the total area of the holding is included, whether that area be of cultivatable land, rough grazing, waste mountain, or the area occupied by buildings. As a result, the contrast between the number and size of holdings in Great Britain and in Ireland is more marked than would appear from the published statistics. Out of 401,445 holdings exceeding 5 acres in Great Britain, no less 232,966 had a cultivatable area of between 5 and 50 acres. If even a considerable allowance is made for farms consisting largely of mountain and rough pasture, it is evident that the number of small holdings in Great Britain is very large, and that the question of the economic position and the extension of these holdings is of wide interest.

2. *Changes in Agricultural Economic Conditions.*—Three main lines of evidence must be referred to:—(1) The changes in the area under tillage and in the numbers of live stock; (2) the increase in agricultural imports; and (3) the movements of agricultural prices. These three points are intimately connected with one another, and bear jointly and severally on the small holdings question. For a good system of small holdings involves an increase in tillage, and the development of agricultural imports and the changes in agricultural prices are among the best tests as to the state of supply and demand in regard to the classes of produce which must be the staple of the small holder.

With regard to butter, the value of the annual imports shows the enormous field which there is for development in the United Kingdom. This, however, involves, if profitably carried out, the improvement of the milk production of our cows—as has been the case in Denmark—and, with an extended crop area, an increase in the number of cows. With regard to the prices of butter, while it is very difficult to compare present-day prices with those of past years, owing to the much greater differentiation which has taken place in agricultural produce, it is clear that the good qualities of butter are realising remunerative prices, and that, for the higher grades of butter, prices have been rising in recent years. There are creameries which are obtaining 1s. per pound for their butter the year round, and, at the same time, there are butters which are only realising half this amount. Anyone who has looked into the question of the prices obtained for butter in different parts of the country, and the astonishing difference there is in the quality of the butter and the causes of this difference, must feel that there is room for great improvement in the butter production of the United Kingdom. But in order to supply to a large extent our demand, and to obtain more remunerative prices, winter dairying must be developed, and this again depends on the extension of the area of winter-feeding crops.

To a somewhat less extent than in the case of butter, grading has affected the comparison of the prices of eggs, but whether one regards the import figures of the past twenty years, or whether one looks to the record of home prices, there is evidence of an upward tendency in the price of eggs. Every year since 1902 has shown better prices being obtained for Irish eggs. Again, it is plain that the output of eggs in the United Kingdom could be enormously increased. So far as Ireland is concerned, there is evidence that it is at the present time steadily advancing, and the export in the year 1904 exceeded a value of £2,000,000. What is true of eggs is true of poultry, and, in general, of all classes of fresh produce. The system of grading has led to better prices.

Considering on the one hand the demand for agricultural produce, as shown by the quantity imported and by the range of prices, and, on the other hand, the economic conditions which determine production as amongst the various competing countries of to-day and of the immediate future, the conclusion to which one is forced is that the future of agriculture in the United Kingdom, especially in the case of the small holder, must depend to an increasing extent on dairy produce, eggs and poultry, fruit, vegetables, and perishable produce, as well as on the production of the best grades of beef. Behind all this the fundamental question is the growing of grain, roots, and green crops, which are the raw material of all the animal produce.

3. *Conditions Essential to the Economic Development of a Small Farm Holding.*—The further question which remains for consideration is that of the capacity of the small holder as a producer and the essential conditions for him of economic production. It is a matter of considerable difficulty either to ascertain what might be regarded as the present average productive capacity of an agricultural small holding or to set up what may be considered a high but nevertheless attainable standard of production. If this is to be done it is necessary to define the size and type of small holding and then to obtain as complete a balance sheet as possible of expenditure and income. Inquiries which have been made in Ireland into the average productive capacity of, for example, the 20-acre farm, show how difficult it is to obtain correct and complete information regarding the average production and cost of such farms. In some cases, reckoning up the various items of expenditure and income, the small holder of 20 acres of average land appears to have only a balance of £30 to £40—plus a house, as net income - after interest on capital has been deducted. In other cases the net income runs from £60 to £70. The small holding is thus a business in which both industry and wise management are essential to success, and the more one studies the economic position of the small holder and sees the forces with which he has to compete

and the limited income which he can realise, the clearer does it become that the problem of the success of the small holder is largely the question of the man. We require the small farmer who has got into his head the sense of comparative values. For the economy of the small holder depends on whether you are going to have the man who sees to it that he has cows and feeds them to give him 800 gallons of milk rather than 400, that he keeps only those hens which give him 140 eggs and not 80, that he gets 10 tons of potatoes to his acre instead of 5, that he joins with others to buy and sell on the most economic lines, that he grows to a large extent his own food and his beasts food, that he feeds his cattle and pigs rationally, and, in a word, that he is alive as an individual to all the small economies, as well as the larger ones, which contribute to prosperity. This question of the man is absolutely at the root of the whole question of success or failure. And it is for this reason that, in view of the remarkable changes and advances in the scientific and the economic conditions of present day farming, that a thorough system of rural education and organisation must accompany the providing of facilities of land and capital for small holdings.

RICE MANUFACTURE.*

The conditioning, husking, and cleaning of paddy, or "the manufacture of rice," as it is briefly termed in America, being associated in this country with the cultivation of paddy, has so far received very little attention; but in America, Burma, and Siam it is worked as a manufacturing industry, which is the more correct system, as the processes relating thereto are quite distinct from the agricultural operations connected with paddy. This system of separating the agriculture and manufacture of a great produce has been adopted in India with regard to wheat, and there are sufficient grounds for introducing it in the case of paddy. The manufacture of rice in this country is an extensive industry. The value of rice produced here far exceeds the value of all the other agricultural produce of India put together. At the opening of the Pusa Institute, the Revenue and Agricultural Member Sir Denzil Ibbetson said that he calculated the total value of the agricultural produce of India to be £349 millions, and the "Agricultural Statistics of India" shows that about 29 million tons of rice, valued at £190 millions, are annually prepared in this country. The preparation of rice is, therefore, the most valuable manufacturing industry in India, and if the statistics of other great manufactures were examined, I should not be surprised if it turned out to be the most valuable manufacturing industry in the world. This enormous industry is, however, being conducted at present on the most primitive methods which are extremely slow, laborious and expensive, to persist in which would not be sound economy. Apart from the question of reducing the cost of production and thereby lowering the price of the staple food of this country, when you consider the vast amount of time and labour wasted on this industry which may be more profitably employed in others—of which the cultivation and manufacture of cotton may be named—you will agree with me that our industrial economics is still in a very backward condition and urgently needs a proper adjustment. Public attention has already been drawn to this manufacture by the *Statesman* newspaper. Considering the vastness of the industry, and the bright vista of economic possibilities it opens up before us, I think this subject commends itself to our very serious consideration. Having manufactured rice for a few years in this province, I think I am able to form some idea of the improvements that may be made in this industry.

The indigenous method of rice preparation, in which the pounder (*dhaki*) or the mortar and pestle (*hath-masuli*) plays an important part, is too well-known to need description. The method, apart from being extremely crude, tedious, and expensive, does not yield a clean produce free from impurities. The average cost of preparation by this method is 6½ as. [1 anna = 1d.] per maund [1 Madras maund = 25 lbs.] of rice, considering the low value of agricultural labour in this country. This cost increases to about 7 as. for boiled (*ushna*) rice and decreases to about 6 as. for unboiled or sun-dried (*alloh* or *attob*) rice. The working time required by one person to prepare a maund of boiled rice by this method is about 21 hours. This is made up as follows:—1 hour for paddy-clearing, ½ hour for putting into and taking out of water the paddy (the soaking which occupies about 24 hours requiring no attention), 2 hours for boiling and 1½ hour for drying it (although the paddy remains in the sun for about 5 hours) one person working all this time. The husking and cleaning of the paddy in the Dhaki is always done by two persons who would together take about 8 hours. For purpose of calculation this would be equivalent to 16 hours for one person, making up a total of 21 working hours. Similarly, a maund of unboiled rice would take about 1 hour for clearing, 1 hour for drying and 16 hours for husking and cleaning, making up a total of 18 workiug hours. Calculating the value of the labour at 3 as. per day of 9 working hours, the cost of 21 hours' labour would be 7 as. and of 18 hours' 6 as. being respectively the cost of preparing boiled and unboiled rice. This average cost of 6½ as, also coincides with the rate paid to hired-workers for rice preparation in certain parts of Bengal which is generally 6 as. per maund of rice, the worker retaining the half a maund of husk which may be valued at half an anna.

Before going further into this subject, it may be mentioned that the cost of rice manufacture varies mostly with the qnality of the rice wanted whether boiled or unboiled, polished or unpolished, but that it

* Paper read before the Second Indian Industrial Conference by Mr. Henry H. Ghosh, Calcutta.

also varies slightly with the quality of paddy used. In coarse paddy, the cost is somewhat lower than in fine paddy. The aforesaid cost is for medium qualities only. It may also be observed that a maund of medium quality Bengal paddy would yield about 26 seers of rice, 13 seers of husk (*thush*) and 1 seer of meal (*kuro*); and that the yield of rice increases slightly in coarse paddy and diminishes somewhat in fine paddy.

It would not be possible for me to state within the limits of this paper, the principles upon which rice is manufactured in America and Burma, but I shall here describe in the briefest outline a fairly efficient and economic system by which rice manufacturing may be initiated in this country. This system is very similar in most of its processes to either the Rangoon or the American system, and I may add that I have attained rather satisfactory results from it.

Conditioning.—The Separation of Refraction.—However much Bengal paddy is fanned at the time of purchase there is always a certain per-centage of refraction in it, such as balls of mud, bits of stick and straw, which have to be separated from the grain. When unboiled rice is wanted this is done by a "circular-motion separator," as in Rangoon. This separator consists of a set of sieves circulating in one plane, and requires very little power to drive. When boiled rice is wanted, the separation of refraction is effected by specific gravity in the soaking process.

The Soaking Process.—Previous to being boiled, paddy is soaked in fresh water for about 24 hours which softens the husk and clears it of all admixture. The balls of mud dissolve in the water, the paddy sinks to the bottom of the vat and the bits of stick and straw float up which are then easily removed.

The Boiling Operation.—The paddy is then partially boiled which renders the rice wholesome from the consumer's point of view and facilitates the husking process from the manufacturer's standpoint as we shall presently see. Par-boiling is done over fire in the indigenous method, but I have found that when effected by steam the operation becomes infinitely quicker, far less laborious, and more easy to regulate. This is done in a boiling apparatus where steam is introduced by means of a connecting pipe. No water is needed and decidedly better results are obtained.

The Drying Process.—Whether for boiled or unboiled rice, paddy is dried in the sun by the indigenous system to facilitate the husking operation. How boiling and drying helps the husking is easily explained. Boiling inflates, and drying contracts the body of the grain, the resultant of these two actions is to partially release the husk. Drying alone has this effect to a very slight extent. Unboiled paddy takes about three hours, and boiled paddy about five hours to dry in the sun, but the grain must be stirred now and again.

I may now say that the question of drying boiled paddy has always weighed heavily on the minds of those acquainted with this industry, and interested in its development. In this country there is a very extensive consumption of boiled rice, the unboiled rice being used by very poor people who find it more sustaining. In Burma also both kinds are prepared, perhaps more of the latter, as her exports are of this sort. But in America only unboiled rice is manufactured. This difference of quality is due in a great measure to the various purposes for which the rice of these countries is required. Indian rice is used exclusively for food, Burma rice for food, distillation and starch, and American rice for food and confectionery. But I fear that the difficulty of drying has been greatly exaggerated in this country. Because by the indigenous method even unboiled paddy is dried in the sun before being husked, an erroneous idea prevails among some of us that this process would be needed for this paddy if husked in the machine. But such would not be the case, for both in Rangoon and America unboiled paddy is husked in the mills without any previous process of drying; and various qualities of Bengal paddy, unboiled and without any special drying, have been husked very satisfactorily in the Engelberg and Cowie's Hullers. Of course, it is always understood that well-matured and naturally dried paddy is to be put in the husking machine. The only question with us, therefore, is the drying of boiled paddy. This can always be conducted under a tropical sun to a limited extent. I have myself dried boiled paddy regularly in the sun on a large platform which I am told is also done at the Coconada Rice Mills. Daily a hundred or two hundred maunds of grain can be conveniently dried in this manner if there is sufficient ground for the purpose. But the treatment of larger quantities in this way would become rather cumbrous. Attempts have therefore been made to dry boiled paddy artificially both here and in Burma, but none with any satisfactory result. Hot air has been always used in the process, and though the drying has been somewhat successful, the colour of the rice has never been as clear and white as that of the sun-dried grain. But there is no reason why we should give up hope in this matter when tea and particularly wheat, about the colour of which consumers are very fastidious, are now being artificially dried. Indeed, I believe it is Gibb's wheat dryer that has showed the best results with paddy up to now. and it is quite possible that Messrs. Thomas Robinson and Son, Ltd., of Rochdale, makers of the celebrated Mallinson's Wheat Dryer will be able to present a perfect paddy-dryer if they find a market for it. I may here mention that Mr. Rakhal Dass Khan, rice-huller maker, of Sulkea, has recently suplied to a Chetlah miller a paddy dryer which dries boiled paddy with a certain amount of success. But it does not treat more than about 40 mds. of grain in 8 hours, four coolies working at it. As it stands, therefore, his process is no better nor cheaper than the sun-drying process.

After treatment in the aforesaid manner, the paddy is brought to a condition fit to be husked. There are several machines on the market for preparing rice. In England, rice mill machinery are constructed by Messrs. Hind and Lund, Messrs. William R. Dell

and Son, of London, and other makers. In Germany, F. H. Schulze, of Hamburg, manufactures rice plants, notably a polishing machine which is called his "Pearler." It is, however, noteworthy that some of the best rice-milling machines come from America and Burma.

Husking. —The principle by which paddy is husked in the indigenous method, and which is followed up in all husking machines, is the application of friction and pressure. On a small scale the most complete and satisfactory husking machine is the well-known Engelberg Huller No. 2, which husks about 60 mds. of medium Bengal paddy in eight hours. The price of huller is Rs. 700. Mr. Rakhal Dass Khan of Sulkea has also constructed a rice huller which I believe is giving satisfaction to a Chetlah miller. I am told that it husks about 40 mds. of paddy in eight hours, and only costs Rs. 300. The cost of replacing wearable parts is little compared to the expense of changing the blade and screen in the Engelberg. Khan's huller is therefore well worth a trial. As for the hullers constructed by the late Jogodiswar Ghatak, I regret I am unable to say anything in their favour. But the husking machine that has so far given the best results with Bengal paddy is Cowie's huller, made in Rangoon. The machine entails the erection of a plant (with double fan, elevator, and direct-acting sift), which cannot be done with a small capital. The outturn of this huller, made in different sizes, ranges from 100 to 200 mds. daily of brown rice.

Cleaning.—When paddy is husked it is technically called "brown rice," owing to the brown coating below the husk which now appears. The removal of this coating is called the cleaning process, in which there is more friction applied than pressure. A good cleaner for a small mill has not yet been put on the market. Engelberg Huller No. 1 is about the only machine that serves the purpose if the skin in its lower cylinder is replaced whenever it wears out. Unless this is done the rice gets slightly discoloured. The White Rice Cone made in Rangoon is, however, an excellent cleaner, the product from it satisfying the most exacting market. It has a large capacity, but is an expensive machine.

Polishing.—When brown rice is cleaned it is technically khown as "white rice." Polishing is the process by which the surface of white rice is glazed. This treatment is only necessary for rice that is exported. Schulze's Pearler has turned out perfectly polished rice at the Ramkristopur Rice Mills Ld.

Rice cleaning and polishing, which is a portion of the industry here advocated, is not new to the country. This system of rice milling entirely for the export trade has been carried on for several years at Ramkristopur and Chetlah near Calcutta, and the complete manufacture of rice is now conducted by a handful of millers scattered about in North Western India and the Madras Presidency. But the only reason I can attribute to the slow growth of the industry is that, unlike the other countries, boiled rice is largely consumed here and the difficulty of paddy drying has always loomed very large in the minds of those that have from time to time been enquiring about it. Had they been reasonable in their apprehensions, the problem of drying might have been solved ere this. I have often tried to correct false notions regarding this industry but my endeavours have been futile.

By the system above stated the cost of rice preparation per maund would be approximately 2 as. 6 p. [2½d.] for unboiled and 3 as. for boiled rice, unpolished, such as would be needed for home consumption. Rangoon millers reckon an average of 3 as. as the cost of preparing polished rice. If a system of artificial drying is introduced, the cost of boiled rice should be reduced by 6 pies approximately. It will, therefore, be evident that by the introduction of the Rangoon and American systems of manufacture, the price of the greatest staple food of our country will be reduced by about four annas on the maund, and an enormous quantity of labour will be set free for more profitable industries.

TRANSPORTATION OF FRESH FRUIT FROM HAWAII TO THE UNITED STATES.*

An opportunity having arisen, it gives me pleasure to write on a subject which is not only of interest to my country and its people, but may also be of interest to the Society of Arts and to the commercial world at large, from the fact that these mid-Pacific Islands, mere specks in the map of the world, are now an isolated insular possession of the United States of America. What follows will also go to show that the people are alive to their own and their country's interest and welfare.

During the session of the Fourth Territorial Legislature, which prorogued, or as the term now in use, adjourned *sine die*, on the 1st May, a Bill was introduced in the House of Representatives by the Honourable Charles Akau, a native Hawaiian member from the First Representative District, Island of Hawaii, on April 4th last, entitled "An Act to promote, provide for and regulate cheap and proper transportation by land and sea of fresh fruit and other fruit from certain points of the territory of Hawaii to the Pacific coast of the United States of America, to provide for and superintend the sale thereof and to authorise the making and promulgation of rules and regulations in connection with the objects aforesaid and the penal enforcement thereof."

The said Bill passed through all the necessary legislative stages both in the lower House, its place of origin, as well as in the upper body, the Senate, finally going to the Governor on the 1st instant, who in turn failed to give it his approval by pocket-vetoing the same.

* Communicated by Mr. F. J. Testa, of Honolulu, Member of the Society of Arts.

At the second reading stage in both branches of the Legislature, the House Committee on Agriculture, Manufactures, Forestry Promotion and Immigration, reported favourably, which report was adopted. In the Senate an oral report was made by the Committee on Ways and Means, and upon motion being thereto made it readily passed the second reading; the third reading following, as a matter of course, upon recommendations thereto respectively made. The House amendments were made on the second reading, and those by the Senate on the third reading respectively, the latter's amendments being readily concurred in by the House upon its return on April 30th, the Bill, as amended, being finally transmitted to the Executive as before mentioned. Thus much for the legislative action taken upon the measure.

Much has been written and said in the past, and chiefly since annexation, about "diversified industries" and "small farming," as well as the creation of interest in having our unoccupied lands replete with "settlers" and "homesteaders." Laws were heretofore enacted, as well as during the recent Legislature, to aid and encourage diversified industries by exempting the lands for the cultivation of certain commercial products from taxation for a stated number of years.

The aid and encouragement was first adopted in 1903 by the exemption of "sisal fibre, castor oil, vanilla extract, Hawaiian starch, pineapple, and Manioca starch (Kasawa);" in 1905, this list was enlarged by the addition of "tobacco, rubber, cork oak, Manila hemp, sansaveria salonica hemp, and cacao," and in "copra" and "grapes for the manufacture of wine" (the whole list being specifically "for commercial purposes") were further added. An attempt was made to place coffee on the list, but this did not pass. Few, indeed, have availed themselves of this advantage, the chief and greatest drawback being the market and transportation, facilities being few and far between.

Local markets are few and the demand limited. Transportation is the most difficult feature in the whole situation. Homesteaders are settled at distances from the landings, so that travelling is generally accompanied by hardship and much labour, the whole being costly and expensive, and by the time the products arrive at their destination, and when returns come in, the receipts are insufficient to pay expenses, including time wasted and labour lost. It is thus that the poor man, or the man of small means, is forced to give up in disgust. While no money can be made, still a meagre living might be eked out by those more persevering and a home ensured. But how many care to eke out a precarious existence in such manner, even in this far away portion of this universe, enriching only the handlers and the transporters, besides those who are already rich, backed by large capital, and ready to cramp and freeze out those unable to help themselves any further on the road downwards. Some few, exceedingly few, have come out with enough for the "rainy day," and they are only those who have held on and disposed of their holdings, or interests, to the larger industry (sugar).

The object of the Bill is to aid and encourage the man of small means by supplying him with a market for his products, as well as the means of transporting the same, for the measure carries a subsidy with it. Probably it was this subsidy that caused its rejection by the Governor, he having called attention in some of his veto messages to various measures introduced this session carrying special items of appropriation.

In my opinion, the measure (House Bill No. 196 herein enclosed and referred to) should have become a law this time, and should it be a "dead letter" even during the interregnum, it could have given the Government, say, two years at the most, to work on the matter for final ratification at the next Legislature in 1909. It certainly was an important measure to the upbuilding of the country, and a great step forward in our material development.

The introducer, a young man and a native like your correspondent, desired not to push it, being content to let it rest till the next session.

Honolulu, May 15, 1907.

THE BILL REFERRED TO ABOVE.

An Act, to promote, provide for, and regulate cheap and proper transportation by land and sea of fresh fruit, vegetables, and other freight, from certain points of the territory of Hawaii to the Pacific Coast of the United States of America, to provide for and superintend the sale thereof, and to authorise the making and promulgation of rules and regulations in connection with the objects aforesaid and the penal enforcement thereof.

Be it enacted by the Legislature of the territory of Hawaii:—

Section 1.—The Board of Agriculture and Forestry, by and with the consent of the Governor, is hereby authorised to negotiate and enter into a contract for a term not exceeding ten (10) years with any responsible person or persons and corporation or corporations jointly or severally to promote, provide for, and regulate cheap and proper transportation by land and sea of fresh fruit, vegetables and other freight from any station (present or future) at and from any point throughout the territory, or from any harbors therein, to the port of San Francisco and all other ports on the Pacific Coast of the United States of America, and to contract and agree with such person or persons, and corporation or corporations, for and in the name of the territory; to pay by way of subsidy to such person or persons, and corporation or corporations, a sum not to exceed fifty thousand dollars ($50,000) annually during said term.

Section 2.—The purpose of this Act is primarily to stimulate and build up the cultivation and transportation of fresh fruit and vegetables from this territory to the mainland of the United States. It is further declared essential to secure the aforesaid result that all fruits and vegetables transported

under the provisions of this Act shall be well packed and of standard quality and size and pass Government inspection to entitle the owners thereof to transport the same under the provisions of this Act; that depots or stations at short distances apart may be established wherever deemed necessary where fruit and vegetables may be left by the growers thereof for through transportation; that a cheap through rate from said stations to the Pacific Coast be obtained; and that said fruit and vegetables be adequately and specially equipped and prepared and otherwise fit for transportation. If the supply of freight offered exceeds the means of transportation at any one time, that the offerings of fresh fruit and vegetables shall be given preference over other freight, and the offerings of fruit and vegetables by small holders be given preference over other offerings of fruit and vegetables; and that the territory maintain an agent upon the coast to maintain proper prices for fruit and vegetables; promote the advantageous transportation thereof inland from the Pacific Coast ports and the prompt sale thereof. And the Board of Agriculture and Forestry is hereby directed by and with the advice and consent of the Governor to contract as far as practicable so as to secure to said fruit and vegetable growers the protection, benefits and means and method of transportation outlined and set forth in this section.

Section 3. — The Board of Agriculture and Forestry, by and with the consent of the Governor, is authorised to make and promulgate all necessary and proper rules and regulations controlling the selection and transportation of fruits and vegetables; the receipt, transportation and delivery thereof to Pacific Coast ports; the transportation and sale thereof after arriving at such ports, speedy and cheap enforcement of damage claims by shippers and all other matters and things to be done or performed under the provisions of this Act, and to provide penalties for the non-observance of such rules and regulations, and for the enforcement of such penalties. Such penalties, which shall be enforcible penally, shall be limited to fines and shall not in any case exceed two hundred dollars ($200) for any one violation of such rules and regulations.

Section 4.—This Act shall go into force and effect from and after the date of its approval.

THE DEVELOPMENT OF JAPANESE SHIPBUILDING.

The war has given a great impetus to the shipbuilding and dockyard industry in Japan, which has made remarkable progress during the last few years. The principal shipbuilding yards are at Osaka, Kobe and Nagasaki, and all three are full up with orders. The total area of the Osaka yards is about 34 acres, and about four thousand men are employed. The Kobe yards have a factory area of over 50 acres, and employ eight thousand workmen. The Nagasaki yards are the largest in the country covering some 80 acres of land, and employing over ten thousand men. These shipbuilding yards, however, find their capacity inadequate to meet growing requirements, and are steadily engaged in extending their works. The factory arrangements have much improved. The building of torpedo destroyers is quite a new feature. Already one of these has been launched at Osaka, four at Kobe, and two from Nagasaki. The construction of gunboats for the Chinese Government is going on at Kobe, two of them having already been launched. The building of ships of over 10,000 tons in Japanese yards is now quite common. At Nagasaki, a ship of 13,000 tons is being built for the Toyo Kisen Kaisha, in addition to a ship to take the place of the *Hitachi Maru*, which was destroyed by the Russians during the war. According to the United States Consul-General at Yokohama, work in the smaller yards has also greatly increased since the war. The small shipyards on both banks of the Kidzugwa have hitherto devoted their attentions to the building of wooden vessels of 200 to 300 tons, but these are now able to build iron ships of 800 tons. The yards at Kayokijima, outside Nagasaki harbour, which have hitherto been engaged in repairing work, are fast developing into a complete shipbuilding yard. At Innoshima, Bingo, there are two dockyard companies, one of which possesses two docks, measuring 300 feet and 364 feet respectively, while the other has a dock 410 feet in length, and is about to open another, measuring 300 feet. At Nochi and Kinoe there are two shipbuilding yards, and possessing a dock 200 feet in length. Kinoemaru has long been known as a centre of wooden shipbuilding, and the launching of a ship of from 70 to 150 tons is of very frequent occurrence. The largest dock in Japan is at Nagasaki, which measures 728 feet. The next being at Yokohama, with a dock of 552 feet; the third largest at Hakodate, being 534 feet long. The floating dock, owned by the Nagasaki Company, is 412 feet in length, and is capable of floating a dead weight of 7,000 tons. Another and larger floating dock is now being built by the same company. The docking business, like the shipbuilding, is now in a very prosperous condition in Japan. The technical knowledge of shipbuilding among the Japanese has also made progress, compared with eight or nine years ago, when the *Hitachi Maru* (6,000 tons) was built. At that time, the engineers and mechanics experienced difficulty in building the steamer, but now they are able to build larger vessels with greater ease and expedition. What is necessary in Japanese shipbuilding is the further subdivision of labour among the various departments of the industry. If this is done, shipbuilding can be executed with more despatch. There is scarcely any doubt that with the devefopment of the shipbuilding industry in Japan orders from foreign countries will increase. Subsidies are given by the Government on all ships constructed in Japan for the Japanese. The sum fixed

in the budget for the current fiscal year, under the heading of encouragement to shipbuilding, is only £73 000, which is exclusive of sums paid to existing steamship lines, and Tokyo papers say that it will prove quite insufficient. Speaking broadly, the rate paid for vessels built in Japanese dockyards, and satisfying the required tests, are £2 per ton for the hull, and £1 per horse-power for the boilers. Fourteen vessels, aggregating 55,488 tons, will come within the scope of the provisions, and the subsidy will amount to £230,000, or £240,000, so that there will be a deficiency of something over £150,000. The Government will probably pay it out of the reserves, and embody it in a supplementary budget for the approval of the Diet next session. The tonnage under construction amounts to 55,488 tons for the fourteen vessels ordered. In addition, the Nippon Yusen Kaisha have ordered six vessels of 8,500 tons each, and there are two ships building of 2,800 tons, which will not be eligible for bounty. Thus the total under construction is 22 vessels, aggregating 112,000 tons. A subsidy is paid to mail steamers sailing not only to Europe, America, and Australia, but also to lines engaged in the coasting trade in China, in connection with Japan. These steamers run to all of the important ports in China, going not only to Corea Dalny, Chefoo, Newchwang, Tientsin, Tsingtau Shanghai, and all southern ports, and to the Philippines, but they go 700 miles up the great river Yangtsze to Hankow. At the close of 1903, Japan possessed 657,000 tons of steamers and 320 tons of sailing vessels. In 1905, the steamer tonnage had increased to 939,000 tons, and the sailing tonnage to 336,000, making a total of 1,275,000 tons. The vessels include 338 under 5 years, 331 from 5 to 10 years, 257 from 10 to 15 years, 181 from 15 to 20 years, and 131 up to 25 years, thus leaving only 148 over 25 years old.

COAL PRICES AND EXPORTS.

The outlook for coal consumers throughout the country is far from promising at the present time, on account of the large increases in prices which have taken place in recent months, and which have no prospect of undergoing a reduction within a conceivable period. All classes of consumers, whether engineers, manufacturers, or railway and gas companies, together with users of coal for domestic purposes, are affected more or less by the upward movement, which started about the time when the export duty on coal was abolished at the end of last October, and which is very prominently connected with the transactions in foreign markets. The coal trade was one of the last branches to participate in the general improvement in manufacturing and industrial enterprises during the past two years, but it has made a considerable advance in a comparatively short period, and is doubtless producing a golden harvest for the coalowners. During the five years and a-half of the operation of the export duty on coal the impost yielded to the national exchequer, as recorded in a Treasury return, a total sum exceeding £11,000,000. Now, if this amount was paid by the coalowners or exporters, as has always been their contention, it will be obvious that the removal of the tax has released them from a very severe financial burden; but it is by no means certain that they were called upon actually to defray all, or any, of the shilling per ton duty on coal of the value of six shillings per ton and upwards. If, however, the coal owners' view of the position is accepted as the correct one, they are deriving a double advantage at the present time—first, by not having to pay the export duty; and, secondly, by reason of the large increase both in home and export prices. On the other hand, the wages of the coal miners in most of the producing districts have been raised in recent months, and industrial peace is assured in the federated area and in South Wales for the next two or three years, owing to the binding agreements between the coal owners and the miners. In May alone, according to the memorandum of the Board of Trade, no less than 270,000 coal miners received an advance in wages, or a total of nearly one-third of the aggregate number of miners employed throughout Great Britain.

The general improvement in the trade of the United Kingdom, and the increase in the wages of the miners, are not the only causes which are responsible for the augmentation in the prices of fuel to inland consumers, as the shipments to other countries have largely contributed towards bringing about the present situation of affairs. In fact, the period of industrial prosperity also prevailing in certain continental countries stimulated the exports of British coal during 1906, and it has continued to operate in this direction in the first six months of the current year. Even the defunct export duty, which the coalowners declared was hampering the trade, failed to arrest the progress of the shipments, seeing that the exports of coal increased in every financial year during the time the tax was in force. The abolition of the impost at the end of last October only left two months of 1906 free from its operation. Yet the total exports of coal in that year, exclusive of bunker fuel, amounted to 8,400,000 tons in excess of the exports in 1905, which in turn exhibited an increase of 1,100,000 tons over the preceding year. But exceptional circumstances existed in 1906 on account of the industrial prosperity in Germany, Belgium, and Italy, and the disaster at the French colliery at Courrières, and the subsequent general strike of coal miners in the Nord and the Pas de Calais. It was consequently possible for exporters to maintain the exports of coal to Germany at 7,600,000 tons in 1906, or practically the same quantity as in the preceding year, which was specially advantageous to British exporters owing to the strikes of coal miners both in Germany and Belgium. An enormous advance of 2,700,000 tons took place in the coal shipped to France in 1906, and augmentations were also recorded in the case of

Italy, Holland, Belgium, Sweden, and other countries. The progress has continued this year, and in he first five months the exports show an increase of 2,100,000 tons over the corresponding period of 1906, of which about 80 per cent. represents additional quantities forwarded to Germany, France, Holland, and Belgium.

The continued expansion in the exports of coal is, without doubt, a gratifying event to producers, although, it is to be feared, that in the promotion of the foreign trade in this raw material the needs of home consumers are not receiving all the attention they deserve, especially in the matter of prices. It is, perhaps, easy to understand the development of the export trade to countries which either have no native supplies of coal or an insufficient quantity for their own requirements, as, for instance, France, Italy, Spain, Holland, and certain other countries; but it is difficult to comprehend why every endeavour should be made to increase the exports to any country which has ample supplies of fuel within its own frontiers, when by so doing the exporters cannot derive any permanent advantage. Year in and year out during the present century our coalowners have complained of German competition and loss of markets, and they have, in some cases, been supported by consular statements recording arrivals of German coal at foreign ports. While losses may have been incurred in particular cases, the export trade, as a whole, has not suffered, as is demonstrated by the annually increasing tonnage of shipments. But the coal exporters themselves, unconsciously as it may appear to them, are simply placing facilities in the way of their German rivals, as every ton of coal forwarded to Germany releases a ton of German coal for the export market. In other words, if less British coal were sent to Germany, the latter country would be compelled to use at home a larger quantity of its own production instead of exporting it. It is unfortunate that British coalowners have failed to recognise the importance of the weapon with which they have armed their commercial rivals, and which they are now strengthening month by month. Certain classes of users have to pay for the privilege of involuntarily supporting this reckless competition, and it is, perhaps, not going too far to assert that all consumers at home are being drawn upon to contribute heavily towards it at the present time.—*The Engineer*.

THRIFT IN AMERICA.

Some statistics published by the *Monetary Times* of Toronto, are interesting as indicating the progress of thrift in America. The habit of thrift is especially apparent there. Living is higher than in Europe, and wages are higher, but both the United States and Canada make a creditable show in the matter of savings' bank deposits. There are nearly 8,000,000 savings' depositors in the United States, the deposits amounting to more than 3,500,000,000 dols. At the close of 1906 the average savings in the United States was about 41·13 dols. *per capita*, based upon a total population of 84,500,000 persons, compared with 34·89 dols. *per capita* five years ago. The average amount of money due to each savings depositor at the close of the last calendar year was 433·79 dols., which compares with 412·53 dols. at the close of 1902. The savings depositors now represent a little more than 10 per cent. of the total population, which is double the number of ten years ago. In 1871 there were in Canada 231 post office savings' banks, and 17,153 open accounts with a credit of 2,497,260 dols. In 1905 there were 989 savings' banks, and 165,518 open accounts, with a credit of 45,368,321 dols., increases of 328 per cent., 865 per cent., and 1,713 per cent. In the same period the cash deposits of the Dominion Government savings' banks had increased from 556,669 dols. to 2,817,267 dols., a gain of 2,260,598 dols., or 406 per cent. Taking the business of the post office and Government savings' banks together, the total deposits in 1886 were 15,158,296 dols. In 1896 this sum had decreased to 11,882,307 dols. In 1905 it showed an increase, the total deposits then being 13,574,471 dols. But while the annual deposits of the Government savings' banks have declined during the past twenty years or more, those of the post office savings' banks, until the past two years, increased steadily. The policy of the Dominion Government is to close their savings' banks as occasion offers. A little over a year ago there were twenty-three Government savings' banks, now there are only nineteen. In a few years there will probably be only three or four. Of late years the annual deposits of the post office savings' banks have been less than the annual withdrawals, the figures for 1905 being 10,504,430 dols. and 12,129,101 dols. respectively. Much of the money withdrawn from the Government banks finds its way into the coffers of the chartered banks. They offer the public advantages which the Government institutions do not. For example, the depositor with a bank may obtain his savings without notice. Then again the Canadian banks advertise largely and there is keen competition for business. There are thirty-five chartered banks in the Dominion each striving for the best business. The deposits of the Government savings' banks in the last twelve months declined to the extent of ·2 per cent., while those of the chartered bodies gained by 10·5 per cent. The Government have some thousand offices in which to transact the savings' bank business, the banks have some 1,700 branches in Canada. At the end of March the Government savings banks' accounted for 14,766,828 dols. deposits, while the post office savings banks held 46,897,724 dols. The March bank statement shows deposits in the chartered banks of 657,961,220 dols.

To summarise, the savings of the Dominion are held as follows:—

Deposits in	Dols.
Chartered Banks	567,937,052
Post-office Savings' Banks........	46,897,721
Government Savings' Banks	14,766,828
City and District Savings' Banks ..	19,945,511
Caissie d'Economie	8,414,108
	657,961,220

The following Table shows that bank deposits keep pace with the increasing population :—

	1891.	1901.	March, 1906.
Population (approximate)	4,833,239	5,371,315	6,371,315
	dols.	dols.	dols.
Total bank deposits ...	193,015,474	390,949,482	687,961.220
Deposits *per capita* ...	40	73	131

Against the figures of the United States the Canadian deposits *per capita* look well :—

	1905. dols.		1906. dols.
Canada	95	..	131
United States	39	..	41

Canada is not only very prosperous, she would seem to be very thrifty.

MUD-BINDING GRASSES.

The following notice from the *Kew Bulletin* (No. 5, 1907) bears upon the subject of some of the remarks of Lord Montagu in the discussion on Mr. A. E. Carey's paper on Coast Erosion (see *ante* p. 664).

The question of sea-defence work, now occupying the attention of the Royal Commission on Coast Erosion, is one of great general interest. Much has been recorded with regard to mechanical devices for arresting the removal and promoting the accretion of shingle, while the preservation and fixation of dunes by sand-binding grasses and other sand-loving plants has been dealt with so often that the subject now possesses a voluminous literature of its own. This literature has been fully summarised by Gerhardt in "Handbuch des deutschen Dünenbaues,"* pp. 629–644, Berlin, 1900, to which reference may be made by those who may desire full information on the subject.

The latest and one of the most comprehensive accounts of sand-binding grasses enumerated by Gerhardt is that by Mr. Lamson-Scribner, published in the "Year Book of the United States Department of Agriculture for 1898," pp. 405–420. A perusal of this paper may be recommended to all who desire to find the salient facts clearly presented in a concise manner.

* Handbuch des deutschen Dünenbaues im Auftrage des Kgl. Preuss. Ministerium der öffenlichen Arbeiten und unter Mitwirkung von Dr. Johannes Abromeit, Paul Bock, Dr. Alfred Jentzsch, herausgegeben von Paul Gerhardt; Berlin, 1900, pp. i.-xxviii., 1-656, with 445 figures in the text.

As compared with the effects of vegetation in preserving sandy shores and fixing sandy foreshores, the action of plants in assisting the accretion of mud and in fixing and preserving muddy foreshores has received comparatively little systematic attention. A sketch of these processes as they present themselves in the great Gangetic delta has been given in the "Records of the Botanical Survey of India," vol. ii., No. 4, pp. 231 *et seq.*,* and incidental allusions to the subject are to be found scattered throughout the literature of topographical and geological botany. The subject is, however, one that is of much interest everywhere from the purely scientific point of view, and one that even in this country may be of considerable practical importance.

Giving evidence before the Royal Commission on Coast Erosion, Lord Montagu of Beaulieu is reported as follows: "The mud banks on his property had gradually been increasing very rapidly. The accretion was due to a somewhat extraordinary fact. Some years ago a ship came up Southampton Water from the River Plate with a quantity of rice-grass on board. The seeds of this grass became distributed about the shores of Southampton Water, with the result that the whole of that estuary was now covered with this grass. It was a plant which grew very rapidly and spread in circles, and now the twenty miles from Hurst Castle to Southampton were covered with this grass, as were the mud-banks on his foreshore. The stiff and sharp points caught the seaweed which came over it, causing the bank to increase rapidly in height . . . . . There was no knowledge of the grass, so far as he could understand, up to ten years ago."

To anyone knowing the vegetation of the coast of Southampton Water, it was evident that the grass in question must be a member of the genus *Spartina*, though the names "rice grass" and "sea-rice" are unknown in botanical literature, and unknown, we believe, to those most versed in the popular names of British plants.

* See especially a reference to the action of *Oryza coarctata*, Roxb., at p. 357.

INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

The second International Congress on School Hygiene will be held in London in August next. The meeting promises to be thoroughly representative and international, and it is believed that it will serve a useful purpose by calling public attention in this country to the need for cultivating healthy conditions in child life, by which means the danger of deterioration of the race can be averted.

The first Congress held at Nuremburg in 1904 was very successful, and the large number of foreign visitors, which included a representative deputation from Great Britain, were received and entertained in a most cordial and hospitable manner. The com-

mittee for organising the Congress in London feel that special efforts should be made to ensure that the second meeting shall be even more successful than the first, and to receive and entertain the large number of foreign and colonial visitors in a manner worthy of this country.

It is estimated that an amount of £3,000 will be required for the organisation and reception of the Congress, towards which only £1,300 has been subscribed. The committee appeal to those interested in educational matters and the physical welfare of the children to give their generous support to the Congress.

The President of the Congress is Sir Lauder Brunton, LL.D., M.D., F.R.S. The Sections, with their Presidents, are as follows: — 1. The Physiology and Psychology of Educational Methods and Work, Sir James Crichton-Browne, M.D., LL.D, F.R.S. 2. Medical and Hygienic Inspection in School, Prof. William Osler, LL.D., M.D., D.Sc., F.R.S. 3. The Hygiene of the Teaching Profession, T. J. Macnamara, LL.D., M.P. 4. Instruction in Hygiene for Teachers and Scholars, Sir William J. Collins, M.P., M.D., M.S. 5. Physical Education and Training in Personal Hygiene, Sir John W. Byers, M.A., M.D. 6. Out of School Hygiene, Holiday Camps and Schools, the Relation of Home and the School, Lord Kinnaird. 7. Contagious Diseases, Ill-health, and other Conditions affecting Attendance, Sir Shirley F. Murphy, M.R.C.S. 8. Special Schools for Feeble-Minded and Exceptional Children, W. H. Dickinson, M.P. 9. Special Schools for Blind, and Deaf and Dumb Children, the Right Hon. the Earl of Crewe, P.C. 10. Hygiene of Residential Schools, Clement Dukes, M.D., F.R.C.P. 11. The School Building and its Equipment, Thomas Edward Collcutt, Pres. R.I.B.A.

The lectures before the Congress will be:—

1. "The Effect of School Training on Mental Discipline and Control in Adolescence," by the Right Rev. Bishop Welldon, D.D., Dean of Manchester.

2. "Hygiene du Sport pour les Femmes et Filles," par Mons. le Dr. Doleres, des Hôpitaux de Paris, Membre de l'Académie de Médicine.

3. "Vortrag ueber Beziehungen zwischen Medizin und Paedogogik," von Prof. Dr. med. et phil. Griesbach, Vorsitzender des Allgemeinen deutschen Vereins für Schulgeshundeitspflege, Mülhausen (Elsass).

The set subjects for discussion at four general meetings, to be opened by English, French, and German speakers, will be:—1. Methods for the first and subsequent medical examinations of school children. 2. School work in its relation to: (*a*) The duration of the lessons; (*b*) The sequence of the subjects; (*c*) The season of the year. 4. The lighting and ventilating of class-rooms.

In order, as far as possible, to illustrate practically matters coming under the consideration of the Congress, an Exhibition will be organised and arranged in the University building by the Royal Sanitary Institute, in which the planning, construction, and equipment of school buildings will be illustrated, and school furniture and teaching appliances of all kinds exhibited.

The offices of the Congress are 72, Margaret-street, London, W.

ELECTRIC SMELTING OF IRON ORE.

Allusion was made some time back in the *Board of Trade Journal* to the researches of Dr. Haanel, Dominion Superintendent of Mines, into the question of the production of iron and steel in Canada by the electric process. It is now reported in the same journal from the *Iron Age* (New York) that Dr. Haanel has now presented to his Government a very full report on the results of the experiments in the electro-thermic smelting of Canadian iron ore which were carried out at Sault Ste. Marie early in 1906.

Under "General Remarks," Dr. Haanel expresses some of his most important conclusions. The very best of pig-iron can be made, he says, from Canadian magnetites that are too high in sulphur to be admitted into a blast furnace. He goes on to say:—"It has been proved that ores carrying as much as 1·5 per cent. of sulphur can be converted into the very finest pig-iron by electrical treatment. One fundamental condition, therefore, namely, an abundance of low-priced ore, can safely be calculated upon, as Canada has vast fields of sulphurous ores. Another fundamental condition is cheap water power. In no part of the world are natural water powers of more general occurrence than in Canada.

"With such a price for the energy required, the small consumption of electrode, the cheapness of the ore employed, and the peculiar excellence of the pig-iron produced, electric smelting of iron ores in Canada in properly constructed furnaces, using charcoal or peat-coke made from our peat bogs of enormous extent, may be pronounced commercially feasible."

The results of the experiments are summarised in the report as follows:—

1. Canadian ores, chiefly magnetites, can be economically smelted as hematites by the electro-thermic process.

2. Ores of high sulphur content can be made into pig-iron containing only a few thousandths of 1 per cent. of sulphur.

3. The silicon content can be varied as required for the class of pig-iron to be produced.

4. Charcoal which can be cheaply produced from mill refuse or from wood which could not otherwise be utilised, and peat-coke can be substituted for coke without being briquetted with the ore.

5. A ferro-nickel pig can be produced, practically free from sulphur and of fine quality, from roasted nickeliferous pyrrhatite.

6. Iron ores containing as much as 5 per cent. of

titanium can be successfully treated by the electrothermic process. This conclusion is based upon an experiment made with an ore containing 17·82 per cent. of titanic acid, a pig-iron of good quality being obtained.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department of the Admiralty in April and May :—

April.—New Charts.—3604—Baltic sea, Sweden, east coast :—Stockholm, Skärgärd, southern portion. 3640—France, west coast :—Anse de Benodet. 3654—North American lakes, Lake Erie :—Sandusky bay, eastern portion. 3627—South America, Magellan strait; anchorages in Martinez and Baker channels :—Port Merino Jarpa, Laguera cove, Port Valdes, Port Alvarez, Port Cueri Cueri, Port Valenzuela, Port Brown, Dewet cove, Port Tres Meses, Port Contreras, River Huemules, Port Quellehue, Port Francisco. 3634—Alaska; plans in Prince of Wales island :—McKenzie inlet, Hollis anchorage, Cordova bay and Hetta inlet, Dolomi anchorage and Port Johnson, North arm of Moira sound, Lyman anchorage. 3637—Alaska; plans in the neighbourhood of Chatham strait :—Red Bluff bay, Hoggatt bay, Herring bay and Chapin bay, Gut bay, Surprise harbour and Murder cove. 3653—Alaska :—Whitewater and Chaik bays. 3655—Plans in Alaska :—Resurrection bay. 593—Alaska, Yukon river to point Barrow including Bering strait ; plans :—Anchorage of Chamisso, Port Clarence and Grantley harbour. 3648—Africa, west coast :—Junk river to Cestos bay ; plan :—Grand Bassa. 1257—Korea :—Approaches to Ping Yang inlet and Yalu kiang, Choppeki point to Amunyoku kang (Yalu kiang). 3642—Korea :—A San anchorage and approaches. 3631—Japan, Kiusiu, west coast :—Yanagino seto and approaches. 3639—Japan, plans in the north part of Honshu (Nipou) :—Funakoshi wan, same anchorage, Fuku ura, Nezugaseki ko, Kuji wan. 3641—Australia, south coast :—Nepean bay. New plans and plans added :—472—Harbours and anchorages on the coast Häiti or San Domingo ; plan added—Port Jackson. 2406—Ports in San Domingo plan added :—Port Rincon. 2194—Sketch plan of anchorages in the eastern part of the Celebes ; new plans :—Parigi road, Muton road ; plan added :—Labua sore. 2718—Anchorages on the east coast of the Celebes ; new plans :—Una Una road, Togian bay, Pagimana road.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners.—No. 109—England, east coast :—entrance to the River Humber. 2184—Ireland, south-west coast, including Crookhaven. 1804—France :—Cape St. Sebastian to Cette. 2755—United States, east coast :—Long island sound, sheet II. 761—West Indies, India islands, and Carribean sea, sheet I. 762—West Indies, India islands, and Carribean sea, sheet II. 2088—Africa, south coast :—Umtavuna river to Tugela river. 2137—Gaspar strait. 2636—Strait of Makassar, north part. 1261—Cochin China :—Saigon river to Kam ranh bay. 1459—China, south coast :—Hong Kong harbour. 2409—West coast of Formosa and Pescadores channel. 809—Tasmania :—Frederick Henry and Norfolk bays. 2766—North-east coast of New Guinea. 764—South-west Pacific :—New Hanover, New Ireland, and New Britain. 2532—New Zealand, sheet IX :—Banks peninsula to Otago.

May.—New Charts.—3638—France, south coast : Golfe de Fréjus and Rade d'Agay. 2487—United States, east coast :—Portsmouth harbour. 3659—South America; Ports in Magellan strait :—Canal Condor and Lago de la Botella, Puerto Condor, Puerto Toro, Port Valderrama, Puerto Pomar. 3651—Chile; Plans in the Guaitecas islands.—Port Barrientos, Port Low, Port Melinka. 3626—Borneo :—Dumpil point to Gaya head including Gaya island. 3616—Celebes :—Tomori gulf to Salayar strait including Buton strait and gulf of Boni. 1968—China, east coast :—Formosa island and strait. 1258—Korea, west coast :—Approaches to Seoul, including Techong (Sir James Hall) group. 1969—Japan :—Ozuchi jima to Funoko sima. Plans :—Uno wan. Takamatsu ko. 3629—New Zealand :—Hokitika to Otago harbour including Cook strait. New Plans and Plans added.—2116—Denmark; Little Belt. Plans added :—Aarhus harbour; Svendborg harbour. 158—Italy, chart II.; Cape Cavallo to Civita Vecchia and adjacent islands. Plan added :—Talamone bay. 930—Plans of anchorages between Borneo and New Guinea. New plan :—Wahai and Hatiling bay. 3340—Gulf of Tartary, northern sheet. Plan added : Angevo road. 384—Plans in Tasmania. Plan added :—East bay and Blackman bay. 55—Anchorages in New Britain, New Ireland, and New Guinea. New plan :—Byron strait to Nusa harbour.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners.—1150—England, east coast, river Thames :—Erith to Broadness. 3466—Germany :—Wilhelmshaven. 3261—Germany, Elbe river :—Outer light vessel to Brunsbuttelkoog. 3262—Germany, Elbe river :—Brunsbuttelkoog to Hamburg. 696—Germany :—Kiel harbour. 185—Germany :—Port Swinemünde and approaches to Stettin. 284—Newfoundland :—Cow head harbour to Ste. Geneviève bay. 2843a—United States, east coast :—Chesapeake bay, sheet I. 192—Gulf of Mexico :—Galveston entrance. 40—India, west coast :—Karachi harbour. 2160—Carimata strait. 1342—Cochin China :—Fan-rang bay to Tongking gulf. 775—Cochin China :—Approaches to Haifong. 1741—Canton river, sheet II.

These charts are issued by Mr. J. D. Potter, 145, Minories.

ARTS AND CRAFTS.

Fashion in Pottery.—We talk of the freaks of fashion, but just lately fashion has been pursuing a course which is fairly consistent if not strictly straight. Not so very many years ago the demand was all for things in the manner of the later Louises and of the French Empire—to-day it is English styles of about the same period which are the rage, and the French styles have given place to patterns of the Georgian and early Victorian, and even the mid-Victorian period.

There must be to-day many a housewife and paterfamilias mourning over the disappearance of the furniture of their early married days which was turned out some time back to make room for what was then the latest thing in the way of house adornment—and many a rashly energetic daughter of the house who laments the haste with which, only a few years ago, she abolished the ormolu ornaments, got rid of the "old-fashioned" furniture, and relegated the china of an early period to the nursery and the school-room so effectually that but little remains to tell the tale. Marked as this movement has been in all directions—in designs for wall-paper, cretonne, carpets and furniture to mention only a few instances—it is perhaps peculiarly noticeable in china and pottery. Imitations and reproductions of old continental patterns are, of course, still being made and sold in fair quantities, but the market for revivals of English makes of a century or more ago has enormously increased. For the moment, perhaps, one of the most conspicuous crazes is in favour of reproductions of what is known as "powder blue," but old patterns of all kinds are being rapidly imitated and sold in large quantities. Of course, Chelsea and Bow and Leeds ware are in keeping with the prevailing style of decoration, and that probably has more than a little to do with their popularity. It is more important to the casual buyer that he should be able to say that his latest vases are designed after a style in harmony with the furniture of his room than that they are intrinsically beautiful or even valuable. Thus the great proportion of china and earthenware being turned out and sold in the ordinary shops to-day is not merely on strictly traditional lines, but is for the great part an imitation, and mostly a deliberate copy of work done about a century and a-half ago. This is all the more extraordinary in view of the experiments, and the consequent advances, made in pottery production both at home and abroad.

Modern Pottery.—There has been an opportunity during the last month of seeing very different directions in which pottery manufacture—or rather the production of ornamental pottery—runs when it gets somewhat away from the beaten track. On the one hand, Mr. A. H. Powell has been exhibiting the hand-painted pottery which he has executed for Messrs. Wedgwood, and on the other a larger and more perfect collection of Lancastrian lustre ware than any hitherto shown has been on view in London. It would be difficult to imagine two more different treatments of the same type of material. Indeed, the treatment is so fundamentally different that we are almost tempted to forget that the material is the same. Mr. Powell has not, as some of his critics seem to imagine, revived a lost art by painting on china and earthenware, whether over or under the glaze. The art of painting by hand on china never died out—partly because there has always been a steady demand for a kind of rather elaborately painted work, and partly because for some less pretentious purposes hand-painting is not only better, but actually cheaper than printing would be. He has, however, relied on primitive methods of work, and in many, if not most of his pieces, deliberately sought simplicity. And there is, of course, nothing stereotyped or mechanical about his work, nor does he, though he founds himself at times upon old patterns of various types, hark back to any particular period of design. The main interest of his productions lies in the fact that they are the artist's efforts to express himself, and not an attempt to conform to any particular set of conventions.

The Lancastrian lustre ware is essentially different. It owes its existence to careful and intelligent scientific experiment. Mr. Burton, far from relying on old or rule of thumb methods, has, as those who heard his lectures know, used all the resources of modern knowledge—and used them to produce something which, while in one sense it rivals Persian and Hispano-Moresque work, is in another pre-eminently modern. Of course, in a process like lustre painting the action of the fire counts for much—painting which has to be fired naturally runs the risk of being unexpectedly changed in the oven. No two pieces of such work are exactly alike, nor would they be so even if the designs on them had been printed instead of painted—the fire takes care of that. Yet, for all that, the perfection of the chemical process is shown by the even distribution of the lustre, and the number of pieces in which the effect obtained is quite evidently that which was sought. The designs are for the most part the work of artists employed at the works, and are painted by them straight on to the pots, and these bear the mark of the painter on the base; but there are a few large pots, and those not amongst the least successful, which are decorated after designs by Mr. Walter Crane. It is not always, however, the most elaborately painted pieces which are most pleasing in effect, and it may be said that the broadest designs always work out best.

From hand-painted dinner ware and such like to painted lustre is indeed a far cry, and the two classes of work are too widely apart to admit of direct comparison; for all that, it is impossible to study them both without reflecting that, admirably suited to certain purposes as primitive simplicity may be, there is everthing to be gained by making the most of modern knowledge of all kinds, scientific and mechanical as well as artistic.

Silversmiths' Work.—There has been good and serious silversmiths' work to be seen in London

during the last few weeks. The Artificers' Guild have been holding a special show, which includes, as well as some interesting jewellery by Mr. Bonner and by other workers attached to the guild, another version of Mr. Spencer's Altar cross, and some satisfactory though very simple chalices the workmanship of which, as was to be expected of the guild, is all that could be desired. However, the most important event of the month in this direction is the completion of the large monstrance for the Westminster Cathedral on which Messrs. Omar Ramsden and Alwyn Carr have been working for the last two years. Some parts of the design were on view with the artists' other work in November, but it is only within the last couple of weeks that it has been possible to see the completed work. One is apt to look upon a monstrance as being of necessity a peculiarly ugly piece of church plate. That may be because there are so many of late period and florid design to be seen in cathedral treasuries all over the continent—but it is partly because, from an artistic point of view, the central glass disc is bound to be a sort of anti-climax. Of course, in this monstrance, too, the central disc is of necessity the point to which the surrounding ornament leads up—but there is here nothing florid in design at all. The main outline is cruciform, with small plaques of translucent enamel at the four ends, representing on the one side scenes from New Testament history in strikingly brilliant colours, on the reverse the symbols of the four evangelists in more sombre blues and greens. The ornament surrounding the centre conforms to a square placed so that its corners fall between the four ends of the outer cross. That on one side is a treatment of the vine, that on the other of the wheat ear, in both cases simple and restrained though the somewhat stiff ear of wheat, however appropriate symbolically, is less easily turned to artistic account than the vine. This centre is further surrounded by some strictly conventional clouds—quite flat in treatment—which are as unlike the billowy structures on an ordinary monstrance as the slender rays terminating in amethysts and crystals are unlike the habitual rather wriggling ones. The fact that the monstrance will be carried in procession has had to be taken into account in its fashioning, and the making of so large a piece of plate in a way which shall render it both substantial and light was no easy task. It has, however, been successfully accomplished and the result is a piece of silversmithing worthy both in design and workmanship of the cathedral which it is to adorn.

GENERAL NOTES.

TRADE WITH GREECE.—Reporting upon the trade of the Piraeus and district (Cd. 3283) Mr. Consul Errol McDonall directs the attention of British manufacturers to the desirability of appointing local agents. It is very dangerous, the Consul says, to attempt business without one, but it is more dangerous to appoint one without using the utmost caution. Many cases are known of firms attempting direct trade, and the results have invariably proved, in the long run, disastrous. A local agent who is energetic, and has a thorough knowledge of prevailing conditions, is a valuable and indeed indispensable adjunct to successful trading with Greece. Firms who are well represented have few losses to report, and, as a rule, are well satisfied with the business done on the market.

GRAPHITE DEPOSIT.—The *Queenslander* (Brisbane), in pointing out that the demand for graphite is at present greater than can be supplied, and that adulterated materials are coming into use, calls attention to the existence of an extensive deposit of this valuable material four miles from Netherby railway station, on the North Coast line, Queensland, with a railage of only 30 miles to the port of Maryborough. This deposit, it states, holds out every inducement for an extensive and profitable manufacturing industry being opened up in Australia, as hitherto the production of clean graphite in that country has been unknown, although the mineral has been looked for in many places. The Queensland graphite plumbago mine was opened up three years ago. The development of the mine is extensive, showing a good body of the material about 30 feet thick, with bands of other material through it. The great difficulty was to cut a road down the mountain, which has been done. The material has been shipped to various parts of the world, and is said to have given great satisfaction for all uses.—*Board of Trade Journal.*

THE TRADE OF RÉUNION.—1906 was a trying year for Réunion. The prices of its products was very low, and in the case of sugar, the staple product of the island, below the cost of production. The communes are deeply in debt and unable to pay their functionaries. The local Government owes some 600,000 francs, and was only able to pay the salaries of the colonial functionaries in December by means of an advance from the central Government. A loan of 2,000,000 francs has been applied for in France, and will be granted on certain conditions, but it seems doubtful if the amount will be sufficient to pay outstanding debts, and to set the colony on its feet. This state of things is largely due, as Mr. Consul Maxse points out (Cd. 3283), to the fall in the price of sugar. The year was a very good one as regards quality and quantity, but a very bad one as regards the prices obtained. The average difference between the cost of production and the market price, Mr. Maxse says, is from 10 to 15 per cent. against the planters, Up to the date of the report only about three-fifths of the 1906 crop had been sold. The great fall in the rate of exchange has also hit the planters very hard.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

APPLIED ART SECTION COMMITTEE.

A meeting of the Committee of the Applied Art Section was held on Thursday afternoon, 4th inst. Present: Lewis Foreman Day, F.S.A. (in the chair), Cyril Davenport, F.S.A., A. Lasenby Liberty, Alexander Siemens, R. Phené Spiers, F.S.A., Hugh Stannus, F.R.I.B.A., Carmichael Thomas, Sir Thomas Wardle, with Henry B. Wheatley (Secretary of the Section).

INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section was held on Monday afternoon, the 8th inst. Present: Sir William Lee-Warner, K.C.S.I. (in the chair), Thomas Jewell Bennett, C.I.E., Sir Frederic W. C. Fryer, K.C.S.I., Alexander Rogers, Thomas H. Thornton, C.S.I., D.C.L., Sir Raymond West, K.C.I.E., M.A., LL.D., Arthur N. Wollaston, C.I.E., Lieut.-Col. Sir William Curzon Wyllie, C.V.O., K.C.I.E., Colonel Charles S. Yate, C.S.I., C.M.G., with S. Digby, C.I.E. (Secretary of the Section), and H. B. Wheatley, Assistant Secretary of the Society.

MULREADY PRIZE.

The Council of the Society of Arts are prepared to offer, under the terms of the Mulready Trust, a Gold Medal, or a prize of £20, for competition amongst students of the Schools of Art of the United Kingdom, at the Annual National Competition to be held in 1908.

The prize is offered to the student who obtains the highest awards in the following subjects:—

(*a*.) A finished drawing of imperial size from the nude living model.

(*b*.) A set of time studies on a small scale, from the nude living model, executed in a short time, of varied shortly sustained poses (mounted on not more than two imperial size mounts).

(*c*.) A set of studies of hands and feet from the living model (mounted on not more than two imperial size mounts).

(*d*.) Drawing from the life, including memory life drawing done at the Examination in May, 1908.

No student will be eligible for the award who does not pass in the Examination (*d*) in drawing from the life, and who does not obtain an award for (*a*) the finished drawing of imperial size from the nude living model. The other two subjects are optional.

The works must have been executed between 1st April, 1907, and 31st March, 1908.

The recipient of a prize awarded under this trust in 1892, 1893, 1896, or 1903, cannot compete again.

The drawings, &c., are to be submitted, with other school works, in the usual manner to the Board of Education, South Kensington, in April, 1908. Each competing drawing must be marked "In Competition for the Mulready Prize," *in addition* to being labelled according to the Regulations of the Board of Education.

CONVERSAZIONE.

The Society's Annual Conversazione in the gardens of the Royal Botanic Society, Inner Circle, Regent's-park, took place on Tuesday evening, 9th inst.

The reception was held by Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Chairman,

and the following members of the Council, Sir William Crookes, D.Sc., F.R.S., the Hon. Sir Charles Fremantle, K.C.B., Mr. Robert Kaye Gray, Sir Charles Augustus Hartley, K.C.M.G., Sir John Cameron Lamb, C.B., C.M.G., the Hon. Richard Clere Parsons, M.A., Mr. Carmichael Thomas, and Professor John Millar Thomson, LL.D., F.R.S.

The gardens were illuminated by coloured lanterns and also by "Kitson" incandescent oil lamps. The Corridor and the Victoria House were lighted by "Blanchard" incandescent oil lamps.

A selection of music was performed by the string band of the Royal Marine Light Infantry (Portsmouth Division), conductor, Lieut. George Miller, M.V.O., Mus.Bac. Cantab, in the Conservatory, and by the band of H.M. Coldstream Guards, in the Corridor.

An exhibition of growing and cut roses and other flowers was arranged in a marquee in the grounds by Messrs. W. Paul and Sons, of Waltham Cross, and an exhibition of rhododendrons and foliage plants was also arranged in the Corridor by Messrs. John Waterer and Sons, of Bagshot, Surrey.

The Victoria House, containing the giant water lily (*Victoria Regia*), and a collection of economic and other interesting tropical plants, was open to visitors.

A "Watteau" Pastoral Play in three acts, entitled "La Marquise," was performed in the Gardens by Mr. Patrick Kirwan's Idyllic Players.

A Concert and Entertainment, under the direction of Mr. Patrick Kirwan, was given in the Club-house.

The number of visitors attending the Conversazione was 1,363.

EXAMINATIONS.

The following is the Time Table for 1908 :—

	Monday, April 6. (7—10 p.m.)	Tuesday, April 7. (7—10 p.m.)	Wednesday, April 8. (7—10 p.m.)	Thursday, April 9. (7—10 p.m.)	Friday, April 10. (7—10 p.m.)
Advanced Stage.	Book-keeping. English. Economics. Danish and Norwegian.	Arithmetic. Commercial Law. German. Italian. Spanish.	French. Commercial History and Geography. Typewriting (7.30 to 10 p.m.).	Accounting and Banking. Shorthand (140 and 120 words per minute) (7.15 to 10 p.m.).	Portuguese. Précis-writing. Russian. Swedish. Chinese. Japanese. Hindustani.
Intermediate Stage.	Typewriting (7.30 to 10 p.m.). French. Danish and Norwegian. Commercial History and Geography.	Book-keeping. Précis-writing.	English. Economics. Spanish.	Arithmetic. German. Portuguese. Italian. Russian. Chinese. Japanese. Hindustani.	Swedish. Shorthand (100 and 80 words per minute) (7.15 to 10 p.m.).
Elementary Stage.	Handwriting and Correspondence. French.	German. Italian. Typewriting (7.30 to 10 p.m.).	Book-keeping Spanish.	Shorthand (50 words per minute (7.15 to 10 p.m.).	Commercial Geography. Arithmetic.
Music.		Harmony.	Rudiments of Music (7 to 9 p.m.).		

The last day for receiving entries is March 3.

The special subject for Commercial History and Geography is :—The Dominion of Canada together with Newfoundland.

PROCEEDINGS OF THE SOCIETY.

APPLIED ART SECTION.

Tuesday, May 28th, 8 p.m. SIR JOHN EDWARD BINGHAM, Bart., in the chair.

The paper read was—

SHEFFIELD PLATE AND ELECTRO-PLATE.

By SHERARD COWPER-COLES.

Necessity—thou best of peace makers,
As well as surest prompter of invention.—*Scott.*

Sheffield Plate.—Introduction—Mercurial or fire-gilding—Pyro plating—Close plating—Historical sketch—Method of making the ingot—Rolling the ingot—Tests for old Sheffield plate—Various examples of old Sheffield Plate.

Electro-Plate.—Historical sketch—Processes employed in the making up of Electro-plating—Preparation of the surface to be deposited on—Depositing the silver—Finishing the silver surface—Burnishing—Colouring—Sand blasting—Frosting—Doctoring or ragging—Bright silver-plating—Differential or localised electro-plating — Stripping and dipping—General arrangement of an Electro-plating shop—Electro-deposition of silver alloys—Conclusion.

INTRODUCTION.

Before Sheffield plate, or, more strictly speaking, Sheffield plated ware, was introduced, mercurial, water or fire gilding was much in vogue, and for many centuries was exclusively used for coating copper and brass ecclesiastical plate, chalices, and similar objects. The process consists of brushing over the surface of silver, copper, brass, or bronze alloys with an amalgam of gold and quicksilver and afterwards volatilising the mercury by heat. By repeated application of the amalgam and heating, thick deposits of metal can be obtained. The process of necessity is confined to those metals which combine with mercury to form an amalgam. Damascening has also been employed for gilding surfaces of some dimensions with gold or silver, by forming around the portions to be covered an undercut line or incision.

Pyro plating is closely allied to Sheffield plating. The process consists of burning the more precious metal into the surface to be coated, as its name implies. The coated metal is subjected to heat in a muffle, or other suitable furnace, and when hot, plunged into cold water, the force of contraction causing the coating of silver to penetrate into the pores of the underlying metal, the two metals becoming inseparable by mechanical means. So thoroughly will the silver penetrate the underlying metal that minute portions of silver may be found retained in its pores after laying bare the base metal by grinding. This process, however, is little used, the thickness of the coating obtainable being limited, while the degree of heat required is not less than 450° Fahr., thus prohibiting its application in a large number of instances. Pyro plating is principally adapted to iron and steel goods, which require careful cleansing to ensure the removal from the pores of the iron of all foreign matter, which otherwise would volatilise when the iron came to be heated, causing the deposit to blister, and form a rough unsightly surface.

The method usually employed for preparing iron to be pyro plated is as follows:—All grease is removed by boiling in caustic potash, after which the article to be plated is well scoured with emery and water and steel brushes. It is then made the cathode in a hot alkali solution, and a strong current caused to flow so as to evolve abundance of hydrogen. As soon as the iron or steel assumes a silver appearance, it is quickly removed into the electro-plating vat. Alloys may be formed by the pyro process by electro-depositing a thin coating of one metal upon another, for instance, zinc on copper, and then burning in.

Close plating is another step towards Sheffield plating, and has been carried on in this country for about 200 years, and is used for coating harness and carriage fittings, not that it affords any special advantage, as the process is expensive and troublesome, but principally on account of the prejudice and conservatism of the coachbuilding trade. Close plating consists in coating the iron or steel articles with a thin sheet of standard silver, brass, or other metal, which is secured to the iron by previously tinning it (often called sweating), and then passing a hot soldering iron over the sheet covering metal, the surface being finally brightened by polishing or burnishing by the usual methods.

SHEFFIELD PLATE.

Historical Sketch.—It was in the year 1838 that electro-plating was introduced, which rapidly superseded Sheffield plating, and it is only within the last ten years that Sheffield plate has been largely sought after by collectors.

In the year 1742 Thomas Bolsover, a mechanic, experimented on the uniting of silver and copper, having accidentally fused the two metals whilst repairing the handle of a knife,

which was composed partly of silver and partly of copper. He observed that a coating of silver could readily be applied to copper by bringing the latter metal into contact with molten silver, and that such a process could be adapted to the manufacture of copper sheets which could be fashioned into articles such as snuff boxes, that hitherto had been wrought in solid silver. Joseph Hancock became acquainted with the Bolsover process, and realising its importance, he started a workshop in Sheffield, where he employed the combined metals for producing a variety of articles which had hitherto been made entirely in silver. The process was rapidly brought to perfection, and quickly grew into a large industry in the towns of Sheffield, Birmingham, London and Nottingham.

Method of Making the Ingot.—The process as evolved from the work of Bolsover consists in plating a bar or ingot of copper, from about 1 in. to 1½ in. in thickness, the breadth and length varying according to the size of the sheets required. The bar of copper is well filed, scraped or planed, so as to obtain a surface free from all flaws. A sheet of silver of varying thickness from one-sixth to one-eighth of an inch or more, of the same size as the copper ingot, is likewise prepared, and the two clean surfaces are brought in contact by placing an iron plate about one-quarter of an inch thick and of approximately the same size as the ingot on the silver sheet, the whole being tightly bound together by twisted iron wire. A solution of borax is applied to the edges of the silver; the whole is then heated in a muffle furnace until the silver is just on the point of fusion, when it is quickly removed and allowed to cool. When it is desired to produce a copper sheet covered with silver on both sides, the operation is exactly the same, with the exception that a silver sheet is placed on each side of the ingot, instead of one side only.

Rolling down the Ingot.—The ingot when cool, is freed from scale and oxide by pickling in sulphuric acid and scouring with sand, and is then ready to be rolled down into a sheet of the desired thickness, being annealed from time to time as it becomes too hard for further treatment.

When rolling down the sheet of copper and silver, it occasionally happens that blisters form on the surface, due to imperfect adhesion between the silver and the copper. If the portions which have become blistered cannot be removed when cutting the sheet up into the shapes suitable for the articles to be fashioned, these blisters are broken by pricking, to allow the escape of air; the blister is heated and the silver rubbed down by means of a steel burnisher. Should the blister have burst during the process of rolling the sheet when annealing, it becomes scaly, necessitating the removal of the blistered portion by scraping, and making good by thoroughly cleaning the copper surface, then applying silver leaf to the damaged portion, then heating and rubbing down with a steel burnisher.

In 1784 George Cadman, in partnership with Samuel Roberts, introduced an improvement by soldering on silver edges and mounts, thus protecting those portions most exposed to wear, and covering the unsightly copper edges. The edges or mounts were stamped in thin silver sheet and soft soldered to the Sheffield plate.

Tests for Sheffield Plate.—Modern Sheffield plate made by electro-depositing silver on copper articles is usually readily detected by the thinness of the silver coating as compared with old Sheffield plating, and by a solid silver piece in the centre of the articles, on which the crest or coat of arms was engraved. Another sure indication of Sheffield plate is bands of narrow strips of silver wrapped round the edges and the mounts such as handles and feet, made of silver stampings, and the backs of trays and similar articles being coated with tin, which was done by heating the articles to the melting point of tin, and then wiping the tin over the surface, using a suitable flux, such as zinc chloride. No tin backs or tinned linings are found on modern Sheffield plate. Another distinguishing feature is that soft solder was always employed in making up Sheffield plate, and the mounts also filled with soft solder. A rough or unfinished edge will occasionally afford evidence as to the genuiness of a piece of Sheffield plate.

The only use to which Sheffield plate is put at the present time, is to the manufacture of Reflectors, the rolled bimetallic sheets being cut into circles and then spun or stamped into the desired form.

Marks on Sheffield Plate.—Most of the marks found on Sheffield plate are to be found in Caldicott and Redman's books dealing with Sheffield plate; several of the same marks are found on electro-plate, as some of the former manufacturers of Sheffield plate took up the manufacture of electro-plate. (Fig. 1).

I will now show you some lantern slides illustrative of the various sets of old Sheffield plate.

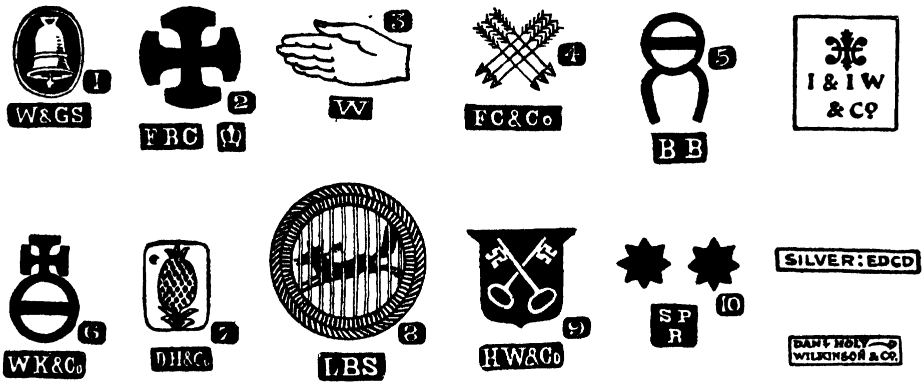
The first is an old Sheffield plate supper or breakfast set on a hot water tray with a gadrooned border. The next slide shows various samples of Sheffield plate, decanter stands, coaster and decanter wagons; the prices realised per pair varies from 35s. to 80s.

The next specimen is an elaborately wrought tray with a crest in the centre, engraved with a coat-of-arms on a silver plate which has became usual when snuffer trays became obsolete towards the middle of last century, to convert them into inkstands. Figs. 2, 3, 4, 5 and 6 show other specimens of Sheffield plate.

ELECTRO-PLATING.

In 1838 Messrs. G. R. and H. Elkington coated military and other metallic

FIG. 1.

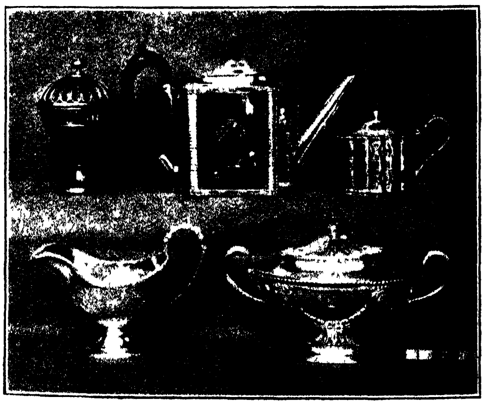


MARKS ON SHEFFIELD PLATE.

been let into the centre of the tray. The centre of this tray is probably not Sheffield plate, but close plating, which has been described, as it would be difficult, or almost impossible, to chase a piece of Sheffield plate so deeply without making the silver coating very thin in places.

The next lantern slide shows a beautiful

FIG. 2.



Sheffield plate wine cooler, with two handles and vine leaf decoration, height about 14 inches. Mr. Caldicott estimates that such a cooler would realise £25 if put up for auction.

The next illustration is a Sheffield plate inkstand, which would realise about £4 each. It

ornaments with silver and gold by immersing them in solutions of those metals. Alexander Parkes at the same time was experimenting for them, with a view of getting thick coherent deposits of gold and silver, the same as had already been obtained with copper by Jacobi, Jordan, and Spencer.

FIG. 3.

Still little progress was made until John Wright, a surgeon, discovered that by the use of cyanide of potassium, thick electro-deposits of silver could be obtained. Cyanides in several forms had been used, about sixteen months before, both for silvering and copper-

ing, by simple immersion, but Parkes was the first to deposit silver by the single cell from the double salt of cyanide of potassium and silver. The first article that received the

FIG. 4.

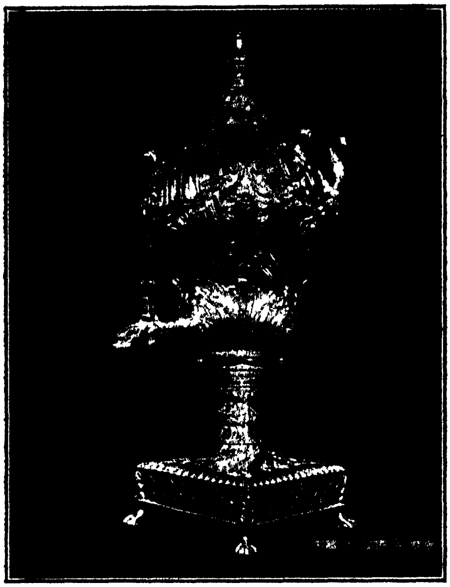


FIG. 5.

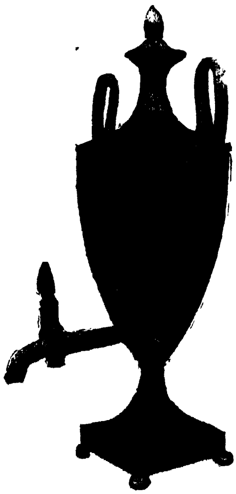


successful coating was a small vase at Wright's residence. The method employed was as follows :—

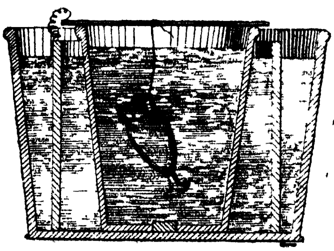
An ordinary garden flower-pot was used as a porous cell, and contained the silver solution; this was arranged in a larger vessel, filled with dilute sulphuric acid. The vase to be coated was placed in the silver solution, and connected by a wire with a sheet of zinc surrounding the porous cell, and immersed in the dilute acid, as shown in Fig. 7.

Wright having submitted his results to Messrs. Elkington, they were embodied by them in a patent, dated March, 1840, and a royalty of one shilling per ounce of silver

FIG. 6.

deposited was paid. This patent proved to be the basis of successful silver plating. After having rendered much valuable assistance in the perfecting of details so essential to the commercial success of any process, Parkes ultimately severed his connection with Messrs. Elkington, and died in 1891, having received a large sum from that firm in recognition of his services.

FIG. 7.



WRIGHT'S EXPERIMENT.

Success had now been attained as far as regards the obtaining of a regular thick deposit of silver, but there still remained various smaller difficulties to be overcome, in consequence of which electro-platers had a hard battle to fight, and it was not until some years afterwards that their trade became remunerative. Want of adhesion between the underlying metal and the silver, which would often peel off, or rise in blisters, under the pressure of the finishing tool, was one of the greatest difficulties which had to be overcome,

and in consequence great opposition was experienced, not only from the manufacturers of Sheffield plate, but from those who retailed their goods.

Imperfect cleansing and want of proper regulation of the electric current had a great deal to do with many of these failures, but the difficulty was not really overcome until Leeson demonstrated that by immersing the articles in an aqueous solution of mercury, and allowing them to receive a very thin film of that metal by chemical exchange before putting them in the plating vat, perfect adhesion could be ensured. The articles thus enfilmed with one of the nobler metals are not easily oxidized, and retain an unaltered surface when exposed to the atmosphere for a period that would suffice to produce a film of oxide on copper, zinc, or their alloys, and thus prevent adhesion. This amalgamating, or "quicking" process as it is called, is only applicable to copper and its alloys. Iron and steel having no affinity for mercury, another method had to be devised for making the silver coating adhere to those metals. It was found that by first electro-depositing in an alkali bath, a thin coating of copper on the iron or steel, and then quicking, the desired end could be obtained.

Of no little importance to the success of the silver-plating industry was the introduction of the dynamo. Even when the single cell method, in which articles to be coated were simply made one of the poles of a battery, had been given up, the only reliable source of current was from primary batteries, which required much attention, and entailed a great expense from the large consumption of zinc. It was not until 1863 that the dynamo made its appearance as a substitute for batteries. One of the earliest machines was that of Wilde, separately excited by a small magneto machine. Not very long after the principle of self-excitation was evolved, Wiener Siemens suggested the series dynamo, and Wheatstone the shunt dynamo.

The extent of the electro-silver plating trade about the year 1880 can be gathered from the following extract from Fontaine's book on "Electrolysis," at which time the majority of the controlling patents had lapsed for twenty years so the number of manufacturers had naturally been increasing but not to any considerable extent, as the important capital required by the high value of the metal has been a bar to many would-be manufacturers. There were not more than ten factories in Paris at that time where the silver plating business was conducted on a really industrial footing. Fontaine states that "The small installations do not succeed, encumbered as they were with general expenditure which prevents them advantageously competing with more powerful and better organised firms."

One single silver-plating establishment in Paris, according to Bouilhet, that of Messrs. Cristofle and Co., annually deposited at that time more than 600 kilogrammes of silver, and since the date of its foundation in 1842, it has used not less than 169,000 kilogrammes of silver deposited upon an incalculable number of objects. The average thickness of the deposits is that which corresponds to 3 grammes per square decimetre, or 300 grammes per square metre, so that the area this factory alone has covered with silver is not less than 563,000 square metres, over 56 hectares (140 acres).

Bouilhet estimated from certain authentic information which he had been enabled to gather that 25 tons was the yearly quantity of silver used in Paris alone for silver-plating purposes, and that if we estimate the producing powers of other countries, which are well known, and compare them with France, he computed the quantity of silver annually deposited by electrolysis in Europe and America at 125,000 kilogrammes (125 tons) which represents an intrinsic value of over 25 millions of francs (£1,000,000 sterling).

The weight of silver deposited at Sheffield alone, in the year 1883, was 300,000 ounces, in round numbers some 8¼ tons. Taking the price of silver at 4s. per ounce its value amounts to upwards of £60,000. If we imagine all this silver deposited at the weight of one ounce per square foot the total surface that it would cover would be nearly seven acres.

The business of replating must always be a growing trade, considering the vast quantity of plated goods which actually flow into the market, and which must, even the best of it, require replating at some time or other.

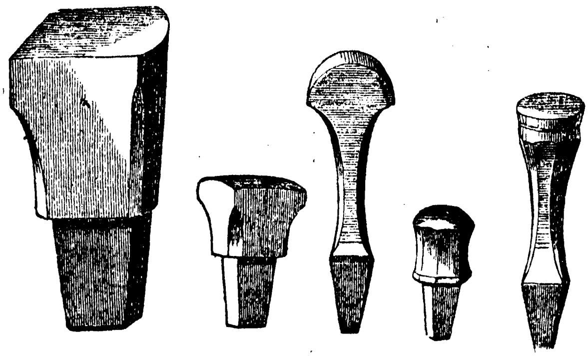
The export of plate, plated and gilt wares, from this country for the year ending 1906, amounted to about £600,000. Of the demand some idea may be formed, when it is remarked that it is the custom with many hotels constantly to employ some four or five hands cleaning over 5,000 spoons and forks daily. It is computed that there are about 170 electro-platers in Sheffield and over 100 in Birmingham.

Hall Marking Electro-Silver Plate.—Hall-marking in Great Britain is confined to a standard silver, but the French and German Governments stamp all electro-silver plate as a guarantee of the actual weight of silver deposited, so that the public may know exactly what they are buying. This precaution, though commendable, must of necessity increase the cost of electro-silver-plated goods, and stifle individual enterprise. Now that the electro-deposition of a standard silver on a commercial scale is an accomplished fact, a careful system of analysis will have to be added to that of weighing, if any importance is to be attached to the Government stamp. The best way the difficulty can be met is, undoubtedly by responsible firms guaranteeing the weight and standard of silver deposited, and marking their goods accordingly.

Making up Electro-Plate.—Time will only permit of my referring very briefly to the principal processes of making up electro-plate from the flat sheet, which are similar to those formerly employed for making up Sheffield plate. The sheet, after it comes from the mill, is annealed and cut into the approximate shape of the article to be fashioned. It is then stamped, spun, or beaten into the desired form. Blanks for spoons are stamped into shape, the blow being given by means of a heavy weight containing half the die; the weight is raised by a belt working over a pulley; when tension is applied to the belt, the friction of the running pulley causes the weight to be raised to the desired height necessary to give the force of blow required.

Another method is to place the flat blank of metal in a lathe against a wood mould of the desired shape, the metal being held in position by means of a centre; a round nosed tool is brought to bear on the metal so as gradually to stretch it over the mould. The metal when it gets too hard is annealed and the process continued until the desired shape is obtained.

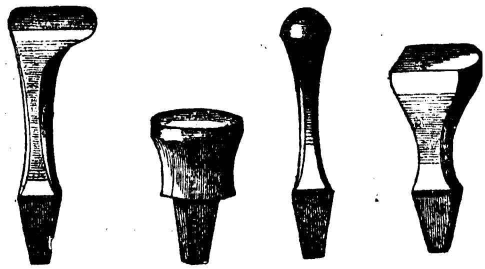
FIG. 8.



ANVIL. LONG HEAD. HALF MOON STAKE. ROUND HEAD. ROUND BOTTOM STAKE.

A third method is to fashion or shape the article by hammering or beating it on a block of hard wood or steel stakes, types of which are shown in Figs. 8 and 9.

FIG. 9.



TEA KETTLE BOTTOM STAKE. OVAL HEAD. PEPPER-BOX TOP HEAD. ANVIL STAKE.

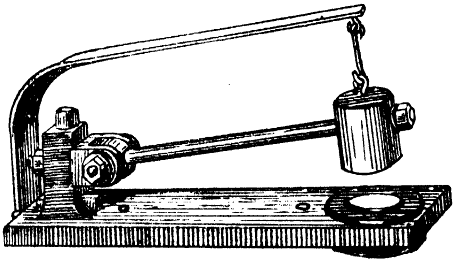
The process of flat hammering renders the surface perfectly smooth and level, and at the same time hardens the metal. Upright steel faced stakes are used embedded in large wood blocks, and the hammers are bright steel of a variety of shapes and weights.

In flat hammering the top side of the article is always kept next to the stake, and the

underneath side of the article kept uppermost whilst it is undergoing hammering, to prevent any hammer marks showing and any dirt which may settle being hammered into the upper surface. To ensure the centre of a tray being true and level it is laid on a large block of iron on which a piece of cloth is placed; the tray is then held firmly, and a tracing punch moved slowly over the surface, the punch being lightly hammered all the time.

Large surfaces are often planished by such an apparatus as shown in Fig. 10, which requires little skill to work as compared to using a planishing hammer.

FIG. 10.

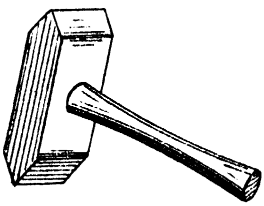


PLANISHING MACHINE.

FIG. 11.

LEATHER-FACED HAMMER FOR REMOVING BRUISES.

FIG. 12.



RAISING MALLET.

For the removal of bruises a leather-faced mallet is employed, Fig. 11.

Raisers or hammermen are those who raise or hammer from the sheet metal; mallets of different sizes and shapes are employed according to the size and shape of articles required, Figs. 12 and 13.

Hammers of different shapes and sizes are also employed, of which Fig. 14 is a type.

Curved work has the hammer marks removed by a hammer such as shown in Fig. 15, often used in conjunction with an elbow stake, Fig. 16, or by a mangling machine, Fig. 17, which, as its name implies, is designed to

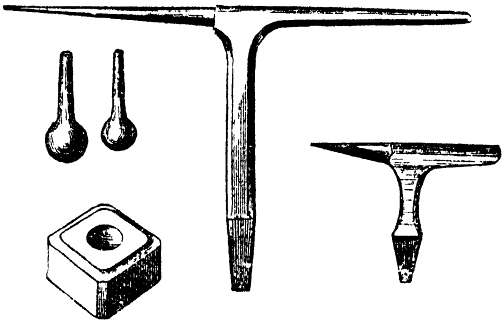
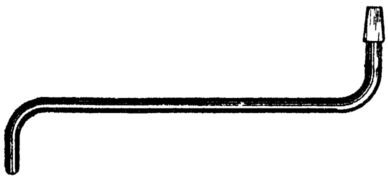
FIG. 21.



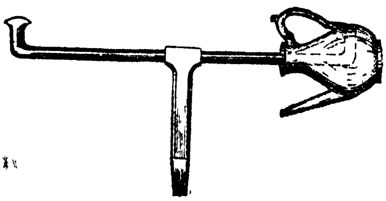
STUD BOX AND PUNCHES. NECK IRON. EXTINGUISHE STAKE.

FIG. 22.



SNARLING IRON.

FIG. 23.



SNARLING IRON.

To put a moulding round an article a suage is often employed, Fig. 18, which is held firmly in a vice and the edge of the article put in the jaws of the suage while it is hammered.

Figs. 19, 20, and 21 show some of the tools employed in making electro-plate and Sheffield plate, the names of which in most cases are a sufficient indication of the principal use to which they are put.

Fluted or chased work is done on pitch; the flutes are raised by the help of a snarling iron (Fig. 22 and 23), unless the fluting has been previously done in the process of stamping. The snarling iron is struck with a hammer near the point of support (Fig. 24), when the iron springs back it strikes the inside of the vessel thus reversing the metal. The article to be fluted is then filled with pitch and chased and is held in position by means of a stirrup, Fig. 25.

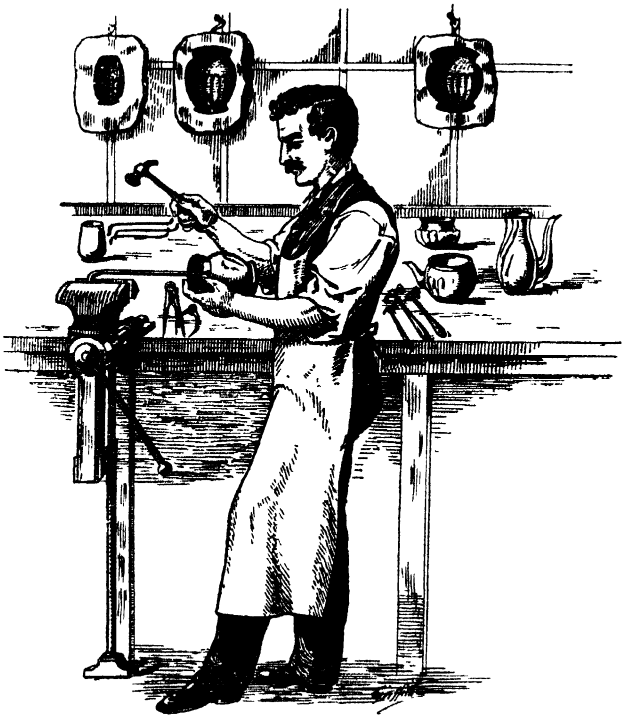
The form of shaving tool employed is shown on Fig. 26.

The engraving of an article is done after it has been made up and finished in every respect. A number of various shaped engraving tools are employed of which Fig. 27 is a type.

The engraving is done by pushing along the line to be cut by means of pressing the palm of the hand on the flat topped wood handle, the work being placed on a leather cushion filled with sand (Fig. 28), or a leather ring, Fig. 29.

The different portions of an article, such as a candlestick, after being stamped, fluted or chased, as already described, are then brazed together with hard or soft solder by means of a gas jet and air pressure.

FIG. 24.



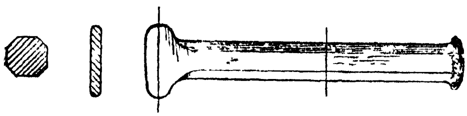
RAISING.

Brazing and Hard Soldering.—There are various methods of brazing and soldering, and dozens of different kinds of solder used. Hard soldering is nearly always done on a turn-table (Fig. 30, which represents a candlestick being hard soldered) on which are usually heaped small pieces of ordinary gas coke which have previously been well burned in a muffle to extract the sulphur. When a more level surface is required than the coke gives, a thick square fire brick or an iron plate is used. Coke is used as much as possible as it requires so little heat to make thoroughly hot, compared to either the fire brick or iron plate. The heat is obtained from gas, and air from a fan

FIG. 25.

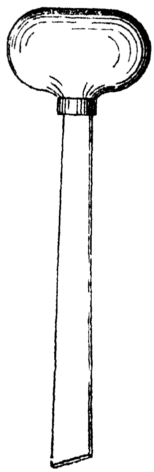
FLUTING.

FIG. 26.



SHAVING TOOL.

FIG. 27.



ENGRAVING TOOL.

worked by power, or from a pair of bellows worked with the foot.

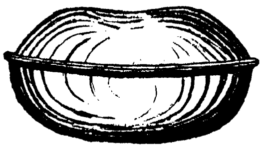
Other methods are adopted for soft soldering and very delicate work requiring hard soldering, mouth blow-pipes and soldering irons being employed. A blow-pipe with a round ball on is commonly used, as it retains a small supply of air whilst the blower takes his breath. Soldering irons are used for soft soldering, and are frequently used to solder and repair places where there is much soft solder near. If a blow-pipe were used, there would be a risk of the other soldered places springing.

For all classes of hard soldering, borax is used in combination with hard solder, and in a similar manner resin and spirits of salts are used for soft soldering. Borax is used either crushed, or finely screened, and mixed with water, or baked and crushed and screened and used dry. The advantage of baking is to prevent it from rising or blowing when the work is heated. Resin and spirits of salts are used differently. Resin is used in powder, and sprinkled on the work; it is also used in lumps to touch the soldering iron. Spirits of salts is also used for Britannia metal work, pewter, &c., and is always "killed" before using by adding spelter or bits of sheet zinc, until it ceases to bubble; a little sal ammoniac is sometimes mixed with it.

The solders used are many. Hard solder for silver is usually composed of—Silver, 1 ounce; brass, 10 dwts. A little arsenic is sometimes added to make it whiter, but this renders it less malleable. A very quick running solder for silver consists of—Silver, 1 ounce; tin, 1 ounce. Hard solders for all classes of nickel or German silver goods, commonly called "brass spelter," is composed of—Copper, 2 parts; zinc, 1 part. This is used either ground up in fine or coarse grains as required, or rolled into a sheet, then cut up into thin strips, or drawn into a wire, and cut up into small pieces for filling stamped handles, mounts, &c. There is also a harder solder employed com-called "white spelter." This requires a very much greater heat to melt, but it makes a very much harder seam afterwards. A solder extensively used and known as "brass spelter" is made of two parts brass to one part silver. To make richer or poorer it merely requires either more silver or brass adding. Solders for copper, iron, and brass, consist of different proportions of copper, brass, and zinc. The proportions depend on the particular kind of work which requires soldering.

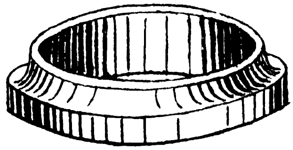
For soft solders, tin and lead only are used.

FIG. 28.



SAND CUSHION.

FIG. 29.



LEATHER RING.

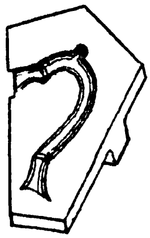
FIG. 30.

BRAZING AND SOLDERING.

For a good solder more tin, and for a poorer solder more lead is used. For a rich solder as much as 1 lb. tin to ½ lb. lead is used, but for a regular class of work more lead is usually employed.

Fig. 30 represents a man soldering a candlestick with a strip of hard solder (two parts brass to one part silver). It will be noticed that the pieces are fastened together with pieces of thin iron binding wire; this is to hold them in their required place whilst the soldering is completed. On the table will be seen two cans, one containing crushed borax, in which the workman dipped his strips of solder when hot, then, after holding the strips in the gas, and having made the article hot, on touching with the strips, still keeping the blast in the same place, the solder will immediately melt, and, if done in a proper manner, and not too much put on, will strike very cleanly, and require very little filling afterwards to make a good clean seam. On the bench at side of the lamp on same illustration will be noticed a teapot with the spout wired on ready for soldering. There is also a teapot body turned up waiting to have the seam soldered with either white or brass spelter, before it is finally shaped. Some round rings also lie on the bench ready to be laid on the brick to be soldered together to make cruet-ring parts. A cake basket is also shown

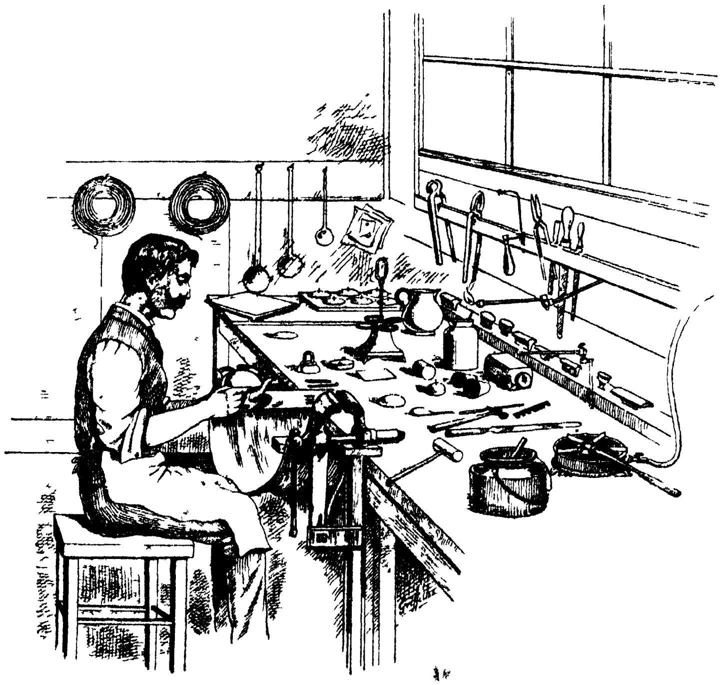
FIG. 31.



LEAD MOULD.

on the bench, with the foot bound firmly on, but not too tightly, awaiting soft soldering. If the binding wires were made too tight, the result would be that on the body getting hot the pressure would be so great that it would give way and sink a little. To move the articles whilst they are hot, several different

FIG. 32.



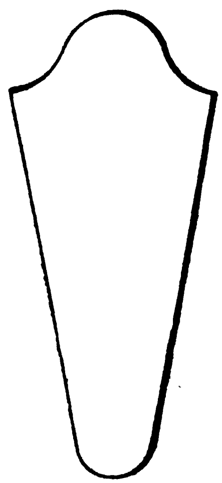
MOUNTING.

shapes of tongues are used; the principal two are the straight and the duck's-head shape. The duck's-head shaped tongs are used so that a good hold can be obtained, as when the work is still hot it is unwise to take hold too near the edge, as the metal is liable to break away. On the bench at the back of the lamp will be seen a teapot handle awaiting soldering. This is put together in two halves, which have been previously stamped and then filed level in a lead mould (Fig. 31). It first receives a thin coating of wet borax inside, and after a little brass spelter has been sprinkled on the borax, the two halves are bound together with binding wire, and heated until the soldier melts. If it does not strike and fill up the seam, a thin piece of iron wire, called a "tickler," is used, the end of which is made hot, dipped in the dry borax, then in a mixture of finely ground brass spelter and dry borax, and when melted the spelter and borax is dropped on to the spot which has been thoroughly heated at the same time ready to receive it. The borax is removed afterwards by "pickling" in a hot vitriol boil. Small things are placed in an earthenware vessel, large articles are suspended by brass wire. The spirit of salts, &c., is removed by cleansing in a caustic potash boil. A careful solderer saves hours of work in finishing which would otherwise be necessary if the work was carelessly brazed.

Mounters are the men who finish tea and coffee sets, entrée dishes, trays, waiters and other bodies, after they have left the hands of the raisers and hammermen. (Fig. 32.) Tea and coffee sets are made in several different ways, for instance the well-known Queen Anne patterns are built up from stampings; in the globe-shaped sets the bodies are raised and hammed as previously described. The handles are usually stamped and soldered together in two halves. In other cases "bodies" are spun on a spinning lathe, or stamping, spinning, raising and hammering are all brought into requisition. Scarcely any two shapes or designs are made identically in the same way. In many instances the work of making tea and coffee sets is divided; one man will raise the hammer, as previously described, and another will mount the pieces. In other cases the same man will both raise, hammer and mount. I will now proceed to give a description of how a teapot, for instance, is mounted.

The spout is turned up from a piece of sheet metal, as shown in Fig. 33, on a pipe stake. The handle is stamped in two halves, which are filed in lead moulds, as already described, so as to make both halves accurately meet; The halves are then soldered together: the domed cover is hammered from a piece of sheet metal on an upright head. The foot is either stamped or turned up from a moulding wire into a ring, to form a foot. After the spout, handle, cover and foot have thus been made, then comes the fitting of them to the body, and piece by piece they are soldered to the body. After the soldering has been done, then the article is pickled or boiled out in a solution of boiling vitriol, about 1 pint of sulphuric acid to a gallon of water, to remove all borax and dirt; they are then filled up, that is, all lumps of solder are filed off, all rough places filed smooth, and all rough edges left by the shears, &c., are finished off with the file. Fig. 32 represents a set mounter filing and finishing off a teapot. Entrée dishes are mounted somewhat differently, the mounts and handles are generally stamped; in some cases

Fig. 33.

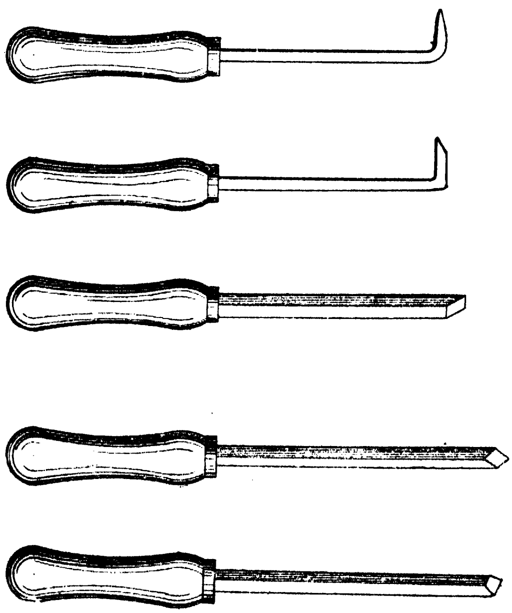


the mounts are turned up from solid wire of the pattern required. Mounts are stamped in different ways, sometimes in one piece; in the case of an oval entrée dish of a regular selling pattern the mounts are stamped in an oval shape. In the case of an uncommon pattern, to spare the expense of this, they are stamped in a straight strip and after they have been filled with brass for hard soldered dishes and soft solder in the case of soft soldered dishes they are bent to any desired shape. The

dish, body and cover are stamped or spun, and after they have been hammered as described elsewhere, they come to the mounter to be "mounted" or made up. After the mounts have been filled, and then filed level and made to fit the dish and cover respectively, they are "sweated" on, that is, as they are already filled with solder, they merely require to be heated so that the solder will strike. The handles are stamped in halves, filled and soldered together in the same way. Different ways and means are adopted for the mounting of different articles, but the principle is much the same as described above throughout.

The cheap tools used by mounters are flat, round, half-round, square, and other shaped files; rifflers shaped and bent to form so as to riffle in places which cannot be got at with a file. Scrapers and scoopers (Fig. 34) of different shapes are used where files cannot be employed.

FIG. 34.



SCRAPERS.

The fashioned article is then ready for the process of electro-plating, which can be roughly divided into three operations:—

(*a*). Preparing the surface to receive the electro deposit.

(*b*). The electro deposition of the metal.

(*c*). Finishing of the electro-deposited metal.

(*To be continued*).

THE COTTON PIECE GOODS TRADE OF SOUTH AMERICA.

Taking South and Central America as a whole, textiles form the most valuable item in the import trade, with the single exception of iron and steel manufactures. In the most thickly populated districts of the entire region, the climatic conditions are such that the clothing of the people must of necessity be composed mainly of cotton goods, and these, accordingly, form the most imporant item of the textile imports. In nearly all the countries, moreover, not only is the population increasing rapidly, but the *per capita* purchasing power is being augmented by development of national resources, and the consequent increase in the production of exportable goods. The demand for cotton manufactures is, therefore, not only large and increasing, but is likely to continue to grow for many years to come. The growing demand is, according to the recent report of a special commissioner appointed by the United States Department of Commerce and Labour, met in two ways—by importation from abroad and by home manufacture. Two of the countries, Brazil and Peru, have large supplies of native-grown raw cotton, and under the stimulus of high protective duties, home manufacture has developed with sufficient success to make it already a factor in determining the amount of imports. One or two other countries, notably Argentina and Uruguay, have followed suit, and have endeavoured to stimulate home manufactures, as well as the production of home-grown raw material by high protective duties, and other means, but they have met with far less success, partly through scarcity of labour for growing the raw material under climatic conditions, which are much less favourable than in Brazil or Peru. They are further handicapped by the lack o abundant fuel or water power for the running of their factories. Their protection of the industry, therefore, rests upon an unnatural basis, and it is not likely that it will result in any very serious competition with imported goods. On the whole, then, it would seem that, in spite of the growth of home manufactures in certain parts of Spanish America, the demand for foreign cottons will continue to increase with the growth of population and the rising purchasing power of the people. South America already furnishes a market for some £16,000,000 worth of European and American cottons, and it is not unlikely that the next few years will see the demand exceeding £20,000,000. The demand is for three or four chief general classes of goods, such, for example, as the finer and more expensive goods for the use of the wealthier classes of the community; plain, unbleached goods, for the making of clothing, flour sacks, &c.; dyed goods, made either from dyed yarn or dyed after weaving; and cheap prints, the demand for which is rapidly increasing. Fine goods of any kind are not manufactured in the native mills, their production being confined to the cheaper, coarser grades. Cheap, plain, unbleached goods, and dyed goods in immense variety of pattern, make up the bulk of the trade, whether

measured by value or by quantity, but the trade in cheap prints, though still relatively small, has made enormous strides in the past few years. So far as native competition is successful, it affects only the imports of the cheapest and coarsest grades of plain and dyed goods. The native spinning is all done by "ring" machines. The heavy sizing in the native mills, both before and after weaving, produces a cloth that cannot be very successfully printed. Nearly everywhere in South America there is evidence that the major part of the increase in demand in recent years has been in dyed goods and in prints. The most accessible field, therefore, for manufacturers, seeking to gain a foothold, lies in the direction of these goods, for which there is an increasing demand. Trade expansion along this line would not preclude expansion in plain bleached or unbleached goods as well; it would merely seem to be the direction in which first advances might best be made. The chief imports of cottons generally are of English and German origin, the former showing a marked tendency to decrease in recent years, while the latter have made equally notable advances. The Germans owe their success mainly to the fact that they have gone into the business on a large scale at a great expense, and with a determination to win. In the first place they carry on what may be called an international producing business. The most successful German manufacturer is not content to sell the products of his own German factory alone, but has purchased, or by contract gained control of the product of factories in other countries as well. There are instances in which a German factory thus controls the output of factories in Italy, Spain, England, France, &c. By this method the German producer has increased the variety of goods which he is able to offer to the South American market, and to maintain his hold on the sales of the particular classes of goods in the production of which his own home factory has special advantages. In the second place, the German exporter almost invariably places the selling of his product in the hands of a German house in South America, a house more or less directly connected with the home concern, and pecuniarily interested in its welfare. The home concern, or the connected house in South America, has in its employ, and constantly in the field, expert travellers, agents, or salesmen, who make detailed and frequent reports on the peculiar demands, not merely in any one country as a whole, but also in the various localities within a single country. These agents are technical experts as well as salesmen, and are able to estimate accurately the cost of making changes of pattern, &c., in response to varying demand, and to quote figures either on the spot or with a minimum of delay. Through their familiarity with the language and their close and frequent contact with the merchants, and even with the consuming public, they are able to form reliable judgments as to the standing of importing and retail firms, and to know at once what changes of fashion have taken place, or are likely to occur in the near future. They are thus able to arrange safely for the granting of the usual six, ten, or twelve months' credit, or for selling on open account, as is not infrequently done, and are able to meet promptly variations in demand. The Special Commissioner says that too many European and American producers sell to the South American market only when they have surplus stock to dispose of, and at such times they make all sorts of concessions, even to the selling of the goods at prices below the actual cost of production. The first step towards expansion of trade, is to convince exporters that there is a trade awaiting development which is valuable in itself, and capable of yielding good profits if properly carried on. With exporters sending out inferior agents, and selling to foreign middlemen, who have no direct interest in the home concern, and therefore use the business mainly as a source of profit to themselves, there cannot be much remuneration to the exporter on such business as is carried on. The middleman's profit, as well as many other items of expense, could be reduced to the benefit of the manufacturer or shipper, if the trade were taken up seriously, as a permanent enterprise. The exporter needs first of all to be convinced that there would be a profit for him in the building up of a permanent trade, and this can be done in only one way. Agents or commissioners must be sent out thoroughly familiar with every detail of the manufacture and trade at home, men who know costs, prices, and customary profits, and all the conditions under which the business is carried on.

AUSTRIAN TECHNICAL SCHOOLS.

To supply the needs of its population in industrial instruction, Austria has evolved a comprehensive system of primary and higher education, which is under the combined supervision of the Ministries of Instruction and Commerce. The schools have justly enjoyed a good reputation among other nations, even serving as models for similar institutions in some countries. The inception of Austrian industrial education was in 1872, the first period of development lasting until 1884. The second period continued until 1894, while the most important development has occurred since that year, the Austrian Government deeming it imperative to employ the most efficient means, owing to the industrial progress of the world, in order to meet competition with foreign countries. The main underlying purpose of the present method is to endeavour to form a close connection and interdependence between school and practice, and is contained in the following school types:—First, schools which give complete instruction in a certain trade. Second, schools in which tradesmen may obtain further instruction in their special trades. Third, schools giving preparatory instruction. The American special agent who has been investigating the systems of technical instruction in Austria, reports that after these twenty-five years' experience

in industrial education, the best results may be said to have been attained by those schools requiring as one of the terms of admission some years' previous practice in workshops, such pupils forming the most promising material, and proving the more eager students. The school types previously mentioned may be divided as follows:—First, central institutions of industrial education with higher aims, as the Austrian Museum for Art and Industry, Industrial Art School, the Technological Trade Museum, Institution for the Graphic Arts, Central Lace Course, and the Art Embroidery School. These in Vienna, with the Technological Museum at Prague, are all State institutions, having an attendance in 1906 of 2,435 pupils. Second, State trade schools, established for the purpose of furnishing general technical education in industrial arts and the trades. While these schools are not entirely uniform, the course of instruction in each occupies four years, and would-be pupils must have passed a period of eight years in the public schools, graduates on leaving these trade schools may become building contractors, independent tradesmen in any of the industrial arts, managers of industrial undertakings, &c. There are at present 21 schools of this type in Austria, having an attendance of 12,566 pupils. Third, special schools for the building trades to afford further instruction to journeymen carpenters, &c. These are a comparatively new departure, and thus far eminently successful in the two institutions already opened, with an attendance of 609 pupils. Fourth, special schools for specific trades. Many of these schools have been established with the object of meeting the particular needs of their respective localities, and, at the present time, there exist of this type, 82 State schools attended by 10,382 pupils, and 75 schools subsidised by the State. Fifth, schools for the handicraftsmen. Of these institutions in Austria, six are maintained by the State, where instruction is given to 2,222 pupils; and five are subsidised. Sixth, special schools for industrial drawing, of which there are four in the Empire. Seventh, general schools for further instruction in the trades, and in drawing. These include instances where the course is in connection with the public school. Altogether they number 1,000 schools, attended by 130,000 pupils. The schools are usually subsidised by the State, and for the most part supported by the municipalities. The Technological Trade Museum of Vienna is one of the most important institutions for industrial education in Austria. The departments comprise those for instruction in the chemical trades, including dyeing, food chemistry, and analysis for instruction in the metal and electro-technical grades, &c. The metal trade department consists of a lower and a higher grade. All pupils seeking admission must have reached the age of fourteen years, passed the examinations of the public school, and be considered physically fit. Such pupils are accepted on two months probation. The instruction covers matters of general education, and all things treated of in the metal industry, *i.e.*, language, mathematics (arithmetic, geometry, algebra, trigonometry, &c.), free-hand drawing, physics, mechanics, mechanical technology of metals, general chemistry (organic and inorganic), trade hygiene, and general practice in workshops. The course for the lower grade is concluded in four years, that of the higher grade for more advanced study necessitating attendance for an additional two years. The formal entrance fee is 3s. 4d., the cost for one year for Austrian youths £10, and for those of other nationality £15. In the department for electro-technics, which is also divided into a lower and higher grade, similar terms of admission (age and public school examination) are required. The lower grade occupies three years, and students are fully taught those things pertaining to electrical science and application. Two additional years are required for completing the course of the higher grade, and graduates are enabled to assume any position in the electrical branches. The entrance fee and cost are the same as those for the metal trade department, but in both instances, where worthy pupils are unable to pay, arrangements are made for partial or entire exemption from all expenses. This department was the second school of the kind to be established, a similar institution at Frankfort, in Germany, being the first. Very much is done by the Ministries of Instruction and Commerce in the way of advancing the trades and handicrafts, all means at their disposal being employed to assist the smaller tradesmen in withstanding the onslaught of the great manufacturing industries, This initiative is followed up by the different provincial authorities. In the Technological Trade Museum at Vienna is also a department, or school, established by the Ministry of Commerce, for furthering its endeavours towards the promotion of the trades. Instruction is given in wood working, metal working, chemical trades, plumbing, carpentry and joining, shoemaking, dressmaking, tailoring, &c. Tuition is here absolutely free, and, in addition, for those pupils coming from outlying districts, scholarships are provided sufficient in amount to defray all necessary living and travelling expenses. Most important and interesting are the small model shops connected with the school in operation, with their necessary attendant foremen and managers, while practical instruction is given in the several trades. Exhibitions of the products of students' labour are held from time to time. The shoemaker's course may be completed in six weeks, and includes anatomy of the feet, measure-taking, cutting, computing, &c. The Government allows scholarships for master shoemakers to the amount of £5, and for journeymen shoemakers to the amount of £4. At the beginning of the present year 975 persons, in 60 courses, had been instructed in these model shops. Six weeks are likewise devoted to the course in tailoring, and the same amount is allowed for scholarships as mentioned above for shoemakers. Fifty-three courses have already been completed, in which 852 pupils received instruction. The joiner's course occupies eight

weeks, during which a knowledge of the scientific treatment of woods is taught. The scholarships in this course are for Viennese master workmen, £7, and for journeymen £6. Thus all participants unable to provide their living expenses during the term of study are supported by grants, while to those living outside Vienna, the re-imbursement or scholarship is for master workmen, £11, and for journeymen, £8, thus making a provision for travelling expenses. The graduates of the 38 courses already completed number 505. Graduates of the carpenter's course, which occupies twelve weeks, are qualified for the position of foremen. These number 293, twenty courses having been given. The students entering upon this course are usually master workmen to whom the Government allows a scholarship to residents of Vienna amountiug to £8, and to non-residents £10. The course of locksmiths and tool-makers is eight weeks. Twenty-five courses have been taken, and 300 pupils graduated. The same amounts are granted for scholarships as in the joiner's course. In galvano-technical instruction, nine courses have already been completed, with a graduate list numbering 101 pupils. Viennese receive a scholarship of £7, others £8. Legal instruction pertaining to the respective courses is given in every case. Since the opening of this institution 3,026 artisans have been given instruction in 205 courses pertaining to their individual trades, the amount of whose subsidies has reached £16,000. The Government also maintains teachers who travel regularly in the provinces, giving similar instruction to pupils in remote country towns.

THE SUEZ CANAL.

In his report on the trade of Port Said and Suez, recently issued (Cd. 3280), Mr. Consul-General Cameron gives some interesting particulars of the expanding accommodation of the canal and its trade. During the last twenty years its navigable dimensions have practically doubled, the superficies of the vertical profile having been increased from 320 to 580 square metres in the ordinary channel, and to 740 square metres in the numerous gares or crossing places, the dredging being so carried out as to exceed the limits originally agreed upon. Between 1898 and 1904, owing to the increasing size of ships, larger gares were begun, some 20 in number, at intervals of three miles, each gare having an effective length of 820 yards, with approaches of 328 yards at either end. At each gare the bottom width of the canal is 50 yards, the width at the water level over 100 yards, the depth of the gare itself being 31 feet. Taking the canal as a whole, its width on the water level in the northern half, is from 100 to 120 yards, and in the southern half from 80 to 100 yards. In 1902 the maximum draught was raised from 25 feet 7 inches to 26 feet 3 inches (8 metres), and on January 1st, 1906, to 27 feet (8 metres 23 centimes). The mean duration of transit remains about the same, namely 18 hours for all vessels, but the general effective rate for mail steamers is 15 hours. The length of the canal is 100 miles, and the ordinary rate of speed is 6¼ miles per hour. The use of the electric light is practically universal, amounting to 97 per cent.

The tendency has been to lower the canal dues, but not rapidly, or to the extent that some think practicable. The original tariff for laden ships was 10 frs. per ton in 1869, which was raised to 13 frs. in 1874, but was lowered ½ fr. per ton from 1877, to 9 frs. in 1893, and to 8½ frs. in 1903. On January 1st, 1906, the tariff was reduced to 7 frs. 75 c., and from the same date the lighthouse dues in the Red Sea have been reduced from 14 to 10 millims. per ton for ships under 800 tons, and from 7 to 5 millims. for ships over that tonnage. For ships in ballast the canal dues have always been 2 frs. 50 c. less. The 10 frs. rate for passengers has never been charged. The transit receipts for last year were 108,161,896 frs., as against 113,866,797 frs. in 1904, the decrease being due to the reduction in the tariff which came into force at the beginning of 1906. 3,975 vessels, of a net tonnage of 13,445,504 tons, passed through the canal in 1906, as compared with 4,116 vessels of 13,134,105 tons in 1905, a decrease of 141 vessels, but an increase of 311,399 tons. It is satisfactory to find that British shipping continues on the whole to hold its own. Out of the total of 3,975 vessels 2,333 were British. The British net tonnage that passed through the canal in 1906 was 8,299,931 tons, a decrease of 57,000 tons as compared with 1905, but representing a percentage of the total tonnage of 61·7. And if only merchant vessels are taken, the British percentage of net tonnage rises to 74·7, the German percentage having risen 1 in recent years, from 15 to 16.

NEW GERMAN METHOD OF SHIPPING LIVE FISH.

The American Consul at Frankfort states that experiments made in Germany with reference to cheap transportation of live fish have demonstrated that all kinds of fish can live for days outside of their natural element, under certain conditions. This apparently wonderful fact will be easily understood by examining the breathing apparatus of fish. The gills of fish are an organ similar to the human lungs; the blood in them comes up close to the surface. The lungs exchange for the outside air, rich in oxygen, carbonic acid which has been formed in the lungs. On the other hand, the gills of fish are constantly washed by water containing oxygen. The thin membrane of the gills separates the blood in them, vitiated with carbonic acid from the water containing oxygen, and the practical result is the same as with the human lungs. Carbonic acid is exchanged for oxygen. It had been noticed long ago that many kinds of fish could live out of water

for some time, provided that the gills remained wet. The experiments made aimed at keeping the gills wet, and to see to it that this moisture be well charged with oxygen. In order to keep the gills wet, the evaporation of the moisture of the gills had to be prevented; for this purpose the fish were placed in an atmosphere thoroughly saturated with water vapour. A wooden box, hermetically closed, was filled with water to the depth of about one-third of an inch, or the bottom was covered with wet rags, which, through evaporation, kept the air in the box always saturated with water vapour. The fish were placed in a box which was then shut hermetically by the lid. Through a tube, reaching to the bottom, oxygen was introduced and allowed to escape through a tube in the lid. This oxygen, before entering the box, passed through several water bottles which thoroughly saturated it with water vapour. In this way the fish are always in a pure oxygen atmosphere, and a drying up of the gills is not to be feared. The result of the experiments was surprising. Carp, tench, and other fish remained in the box for from three to four days perfectly well. When they were then placed into water to be fed, they swam about in a lively manner and appeared perfectly fresh. The Consul says it is expected that this mode of transportation for fish will become popular, as it is much more economical than shipping live fish in water tanks. By the latter method the weight of every shipment was 93 to 96 per cent. water.

LOCAL INDUSTRIES IN PERSIA.

In his report on the trade of Persia just issued (Cd. 3283) Doctor Aganoor, Acting British Consul-General, shows how local industries are declining in Persia. The chief of these industries are cotton and silk weaving, and henna grinding. Many kinds of cotton and silk tissues are manufactured, also carpets called "zeloo." The latter industry seems to be increasing. A coarse gray cloth called "karbaz" is also manufactured. Nearly all articles of local manufacture are both consumed locally and exported to different parts of Persia, but most local industries are gradually declining, as imported articles can be retailed cheaper than articles of local manufacture. Manufacturers abroad are constantly obtaining samples of cotton and silk tissues manufactured in Yezd, which they exactly imitate. Another factor which tends in no small degree to cause the decline of local industries is the excessive "maliat" (taxes) levied by the local authorities on the industries. Only a portion of these taxes is accounted for to the Treasury, the balance being pocketed by the tax gatherer, who has to buy his position. Henna is imported from Bam and Khabis in the Kerman district, and after being ground it is exported to places all over Persia, to the Asiatic provinces of Russia, and to Constantinople. It is used for staining the hair and nails.

HOME INDUSTRIES.

Banks, Dividends, and Investments.—The past half-year was a prosperous one for banking interests. Owing to the condition of the money market profits were unusually large. For example, the Union of London and Smith's realised profits amounting to £279,204, as against £258,039 for the corresponding half-year of 1906; the London, City, and Midland has a sum available for distribution of £505,914, as against £448,663; and so with most of the leading banks. But there is little change in bank dividends. The only noticeable improvement is in the dividend of the Metropolitan Bank (of England and Wales), which is at the rate of 15 per cent. in lieu of 12½. The explanation of these stationary dividends notwithstanding large profit increases, is, of course, the recognition of the need for writing down investments and making provision therefor. As a rule the banks have not definitely stated the figure at which Consols are taken in their balance-sheets. They have contented themselves with setting aside a considerable sum for depreciation of investments; and in many cases the carry forward has been considerably increased. Quite possibly definite announcements will be made at the meetings of the banks. A few years ago some of these banks wrote down their Consols to 85, and in doing so they were thought by many to be unduly pessimistic, but now one bank has actually written down to 83, and there are authorities who consider that the figures should be 80. Whatever the point fixed, it is well to remember that the investments will remain at that figure, for a rise in the market price is not likely to induce auditors to "write up" assets. Meantime the sums set aside for depreciation are in many cases very large. The London, City, and Midland uses £50,000 for writing-down purposes; the London and Westminster has transferred £100,000 from reserve to a Government securities depreciation account; and so in varying proportions but always in considerable amounts. In the past half-year the average Bank of England rate was as high as £4 13s. 10d., in comparison with £3 13s. 11d. in the first six months of 1906, and of £2 13s. 9d. in the corresponding period of 1905. Even at the present level of prices the yields afforded by British Government securities are no more than about 3 per cent., the yield on Consols is still less than 3 per cent., and if the Bank of England's rate of interest averages for a whole half-year £4 13s. 10d., Consols cannot be expected to stand at a figure much over 3 per cent. It is indeed a little surprising, having regard to the immense creations of high class securities in recent years, the demand for money at high rates, and the activity of home industries, that British Government stocks have not depreciated to an even greater extent than that shown by present quotations.

Platinum.—Whatever may be the truth about new discoveries of platinum in Russia and North America, the rumours have had the effect of reducing the price

of this very rare metal very considerably. At one time last year the price was 150s. per ounce, or almost double that of standard gold. Not many years ago it could have been bought at 20s. per ounce. About the middle of April the price fell 20s. per ounce, and since it has receded another 30s., so that the present market price is about 100s. per ounce. Platinum is got, for the most part, from Russia, being found there in alluvial deposits mostly in the Ural districts. A little, too, is got from North and South America, but practically the world has hitherto had to rely upon the Russian supply, and the shrinkage in the Russian output is due to several causes. Since the Japanese war, and the internal divisions in Russia, labour has become scarce, there have been strikes, and more or less stoppage of works. Then the ore is of poorer grade. The mines have been impoverished by the exhaustion of the richest portions, and this entails the handling of a greater tonnage of mineral, which means a greater number of hands and increase in the cost of extraction. It is said that much of the ground worked upon at the present time yields less than 1 dwt. of platinum to the ton, and that even the high class of mineral ground does not produce more than from 2 dwt. to 3 dwt. On the other hand the demand for platinum continues to grow, and is likely to grow even more rapidly in the future. For it is used in many of the most growing industries. It is used largely in the electric lighting industry. Each electric lamp requires two little platinum wires sufficiently long to pass through the glass of the bulb so as to ensure a perfect vacuum, without which the lamps will have no durability, and as the manuacture of these lamps increases by millions a year the demand under this head alone is large. It has been attempted to find substitutes, and it is now claimed that a satisfactory substitute has been discovered, but it remains to be proved. Platinum is said to be the only metal upon which diamonds can be mounted. Platinum is used again in the process of platinotype photographic printing now so common. Then there are the requirements of the dental and chemical industries, and the ignition apparatus of motor cars. Platinum is essential owing to the exceedingly high melting point (1,775 deg. Cent.), which enables it to withstand intense heat. And it resists strong acids. At the moment the trade seems to be sufficiently supplied, but prices are not likely to go much lower. It is not thought probable that the new discoveries of platinum will do more than meet the growing requirements of the various industries using it, if indeed they do as much.

The Tweed Trade.—Probably no trade has been more adversely affected by the rise in the price of raw material than the tweed trade. The principal raw material of the Scotch tweed trade is wool, and for three or four years past the price of wool has been rising steadily, and although there were expectations of reaction in the cheaper grades prices remain at about their highest points. In the case of some grades the rise in price, as compared with former years, amounts to a hundred per cent. But whilst there has been such a serious increase in the price of the raw material the tweed manufacturer has been unable to raise his prices in corresponding degree, or, indeed, at all. The demand is good and increasing. During the last twelve months the South of Scotland tweed trade has been exceptionally busy, and to-day it is as busy, if not busier, than it has been for years. But there is little profit in it for the manufacturer. No adequate advance can be obtained in the price of the manufactured article, so that the greater portion of the advance on the cost of wool has to be borne by the manufacturer. The tailor who supplies the consumer has a standard price for a suit of tweed, and does not see his way to raise the price to his customers, so that he cannot pay more for the cloth to the merchant, who is the middleman between the manufacturer and the retailer. The merchant pays a little more per yard for the cloth which he shares with the retailer, but the brunt of the loss has to be borne by the manufacturer and spinner. It might be thought that this state of things would bring about concerted action between the manufacturers, but this would inevitably lead to substitution of lower qualities, or of mere imitations. In other branches of the textile trade the prices of the manufactured article more or less rise and fall with the cost of the raw material, but, as matters stand, this is not the case with the tweed manufacturer. Already he has to reckon with imitations. Cloths are woven, more particularly in Yorkshire, to imitate Scotch tweeds, and are largely sold as such. These imitations closely resemble the genuine article, and even an expert cannot always detect them at first glance. Made of inferior materials the cloth can be produced at much less cost than the genuine article, and since the recent rise in the price of wool, the trade in it has grown to great dimensions. A committee of the South of Scotland Chamber of Commerce has for some time past been inquiring into this "substitution" trade, but the difficulties in the way are many. Nor is it only from England that the Scotch manufacturers have to reckon with what they consider unfair treatment. A large quantity of foreign spun yarn, mostly Belgian, is used in the manufacture of tweeds, and the Scotch spinners feel the competition of worsted yarns, now used for a very considerable portion of the best Scotch tweeds, one reason being that worsted goods cannot be so successfully imitated in shoddy or woollen goods. Most of the worsted yarns are got from Yorkshire, many of the Scottish manufacturers having dispensed with carding plant altogether. It is surprising that nothing has been done with regard to the registration of a general trade mark to protect goods of Scotch manufacture. The establishment of a standard for Scotch tweeds, defined as "fabrics made from Scotch wool, carded, and spun, and dyed and woven in Scotland," would seem to be very necessary.

Railway Rates for Coal.—Reference was made in these Notes a week or two ago to the alteration in the rates for the carriage of coal, coke, patent fuel, and breeze. The change came into force on July 1st, and has evoked mnch protest. Meetings of coal traders have been held in most of the important centres of the country, and there has been general agreement as to the need for resistance. The London Coal Merchants' Society are preparing a petition to the Board of Trade, but meantime the rates have to be paid. The objections taken to the action of the railway companies are that the notice given was inadequate, seeing that the traders' long contracts have just been entered into, that the increase is equivalent to 2½ per cent. on the charges, and that the change abolishes the old-established custom of an allowance for the "wastage" that is inseparable from shunting operations, &c.

Iron and Steel.—It looks as if the trade of the world in iron and steel has for the present reached its maximum, and that certain declines are to be expected, even though the volume of trade may be intrinsically good. It is noteworthy that Cleveland pig iron warrants have recently dropped to 55s., and that Cumberland hematite warrants have receded to 76s. Both the German and American demand for iron have been continued for an unexpectedly long time, and even in June shipments to both America and Germany were large, but they were nearly all against contracts booked earlier in the year. The new orders are few, and although there is a good deal doing in home industries there is a falling off in new business. The steel trade is fairly active, but activity in shipbuilding is declining. It would seem then, whether regard is had to the indications from abroad or at home, that the abnormal demand for pig iron has ceased, or is about to cease. Once America and Germany leave off taking from us more will come upon the general market, where the consumption is not increasing. In the iron and steel industries, as the rest, the lean years follow the fat.

GENERAL NOTES.

Machinery for Cultivation of Vineyards.—The Paris *Moniteur Officiel du Commerce* of 13th June (quoted in the *Board of Trade Journal*), announces that the Italian Ministry of Agriculture will hold an international competition for machines adapted to the cultivation of vineyards. The competition will take place in Palermo in the course of next autumn. The machine adjudged best will be awarded a diploma and 10,000 lire (about £400) and the Ministry of Agriculture will purchase two of this class; the second prize consists of a gold medal and 3,000 lire (about £120). Applications for admission to the competition must reach the ' Direzione Generale dell' Agricoltura," Rome, by the 15th September next; they should embody full particulars of the dimensions, weight and power of the machines which it is proposed to exhibit, and of their mode of working, and any other details which may be deemed useful.

British Shipping and Rotterdam.—The figures of British shipping which entered the port of Rotterdam in 1906, supplied by Mr. Consul Twining, in his report (Cd. 3283) recently issued, show that the British preponderance was well maintained. Of the total shipping entering the port 39½ per cent. taking numbers, or 38½ per cent. taking tonnage, was British, which compares with 37 and 35 respectively in 1905. Next to the British total of 5,635,371 gross tonnage comes that of Holland, 2,843,079 tons, and Germany, 2,558,666. Taking all nationalities, the gross tonnage entering the port in 1906 was 14,572,246 tons. In the decade 1897-06 the tonnage of the port increased from 8,434,032 tons to the above-quoted figures of 14,572,246 tons. Mr. Consul Twining refers to the reduction in the commission charged for the transmission of wages and the poundage for money orders from 3d. to 1d., and says that there has been a consequent increase in the number of money orders issued. The amount of wages payable in 1906 on the termination of the respective voyages was £80,148 15s. 2d., and of this sum £22,598 13s. 4d., or 28 per cent., was remitted to the United Kingdom by 1,926 men, representing 25 per cent. of the number discharged at the Consulate; the respective percentages in 1905 were 26·44 and 24·28.

Lace and Tulle Manufacture in Calais.—During the last two years the lace and tulle manufacture, the staple industry of Calais, has been very prosperous. In a special report recently published by the United States Consul, and referred to and endorsed by Mr. Consul Payton in his report upon the trade of Calais just issued (Cd. 3283), says that up to December 10, of last year the exportation of Calais lace to the United States alone amounted to £1,660,000, and the completed year would show a total exportion to America of between £1,800,000 and £2,000,000. The Consul had known cases of single invoices amounting to £8,000 and £12,000. He also referred to the enlargement of factories and building of new ones, and stated that lace-workers were earning from £4 to £8 per week. But Mr. Consul Payton says it must be borne in mind that this is principally piece-work, the men being paid so much per rack, and that, while skilled and industrious workers may get paid at the rate, many of them receiving their pay on Saturday do not return to work till Tuesday or even Wednesday. Several small new factories have been built, and one large one increased by a big new wing, which will probably bring its capacity up to about 200 machines. A good machine costs about £1,000 to £1,200.

Journal of the Society of Arts.

No. 2,852. VOL. LV.

FRIDAY, JULY 19, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

EXAMINATIONS.

The results of the Advanced Examinations (Stage III.) have been published and copies have been sent to all centres for distribution to candidates.

The results of the Intermediate Examinations (Stage II.) will be published early in August and of the Elementary (Stage I.) at the end of that month.

PRIZE FOR INDUSTRIAL HYGIENE.

The Council of the Society of Arts are prepared to award, under the terms of the Benjamin Shaw Trust, a Gold Medal, or a prize of £20.

The medal, under the conditions laid down by the testator, is to be given "For any discovery, invention, or newly-devised method for obviating or materially diminishing any risk to life, limb, or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means."

Intending competitors should send in descriptions of their inventions not later than December 31st, 1907, to the Secretary of the Society of Arts, Adelphi, London, W.C.

Such descriptions may be sent in under the inventor's name, or under a motto, accompanied by a sealed envelope enclosing the name, as preferred.

The Judges will be appointed by the Council.

The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the Judges nothing deserving the full award is sent in.

PROCEEDINGS OF THE SOCIETY.

APPLIED ART SECTION.

SHEFFIELD PLATE AND ELECTRO-PLATE.

By Sherard Cowper-Coles.

(*Continued from p.* 866.)

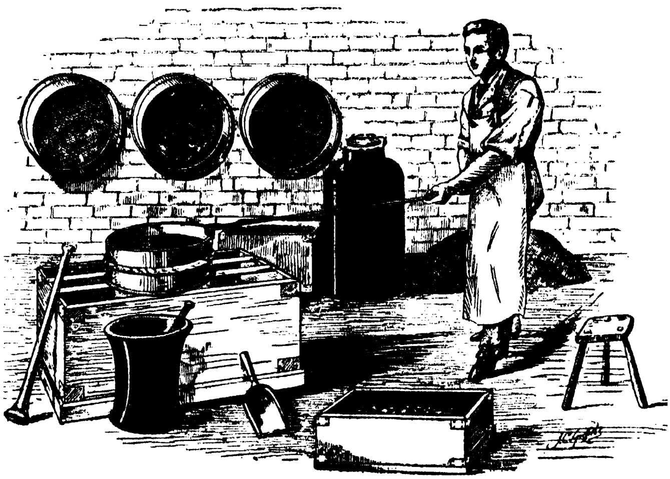
Polishing.—The first operation an article has to undergo when it leaves the hands of the workman who finally fashioned it, is to render the surface quite smooth and free from blemishes and scratches, which is done by a process of abrasion by a polishing or buffing machine. Men and women are employed on this operation, which consists of applying the article to rapidly rotating leather wheels or discs, made out of walrus hide or other hard leather, screwed to the end of a revolving spindle. The abrasive material is fine sand, (mixed with a little oil), which is carefully prepared by a system of grinding and screening, such as shown by lantern slide (Fig. 35). The sand is constantly being lifted from the tray into which it is projected by the revolving discs, and applied to the object under treatment by means of the hands.

When replating old work such as Sheffield plate, the silver is stripped off in an acid solution, and in many cases the article is then scoured by hand, instead of buffing or polishing on a lathe. Scouring is done by means of hard brushes and sharp sand or pumice powder (Fig. 36). If a higher degree of polish is required the wheels or discs composed of layers of calico are used, to which lime is applied instead of sand, the lime being carefully burned and placed in air tight jars until required for use.

Removing Grease and Cleansing.—The next operation is to remove the grease left by the process of polishing and handling, which is done by dipping the articles in a tank of hot

caustic soda, or potash solution, either by placing the articles in baskets or perforated trays (Fig. 37), or dipping them, if of large size suspended by wires or copper hooks (Fig. 38). The objects are usually wiped over

FIG. 35.



PREPARATION OF MATERIALS FOR POLISHING.

FIG. 36.

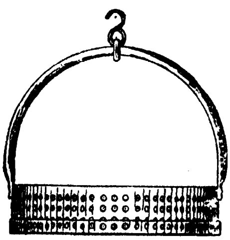
SCOURING.

with a soft cotton mop to ensure the removal of any adherent grease or soap formed by the saponification of the grease. The articles are then rinsed in water and taken to a bench where they are attached to wires by women, ready for suspending in the electro-depositing bath.

The method of wiring such articles as spoons is shown in Fig. 39; the position of the wire is changed several times during the process of depositing silver, so as to avoid wire marks which would otherwise occur.

Quicking.—The next operation is to dip the articles in a solution of cyanide of potassium and mercury, called quicking, to ensure the proper adhesion of the silver coating, after which it is struck, that is, the articles are put

FIG. 37.



DIPPING TRAY.

in a striking vat, where a comparatively high current density is employed, so that the articles become instantly coated with silver when immersed in the electrolyte. They are then removed and thoroughly scratch brushed, that is, brought into contact with rapidly revolving wire brushes on which a weak solution of size or stale beer is allowed to trickle.

Many articles after the polishing and the removal of all grease are dipped in acid to

remove all oxide and then in running water prior to quickening.

Depositing the Silver.—The articles are then placed in the silver depositing vat, Fig. 40,

FIG. 38.

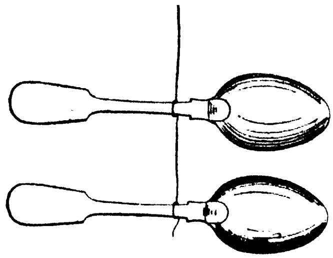
REMOVAL OF GREASE.

FIG. 40.

DEPOSITING VATS.

where they are allowed to remain for a number of hours, according to the thickness of the metal required. The vats are provided with reciprocating or rocking frames so as to keep the solution agitated, and thus ensure a more even distribution of the silver. The anodes or plates through which the electric current

FIG. 39.



METHOD OF WIRING.

passes in the solution, are made of rolled silver, which is cast into bars. The articles are weighed before and after plating, so as to determine the weight of silver deposited, the particulars being registered by means of records. The method of attaching the wires suspending the articles to be plated to the electric conductors is shown in Fig. 41.

Burnishing.—The final process consists of burnishing or polishing the silver, so as to obtain the bright surface usually appertaining to electro-plated articles. If the articles are to be burnished, they are again scratch

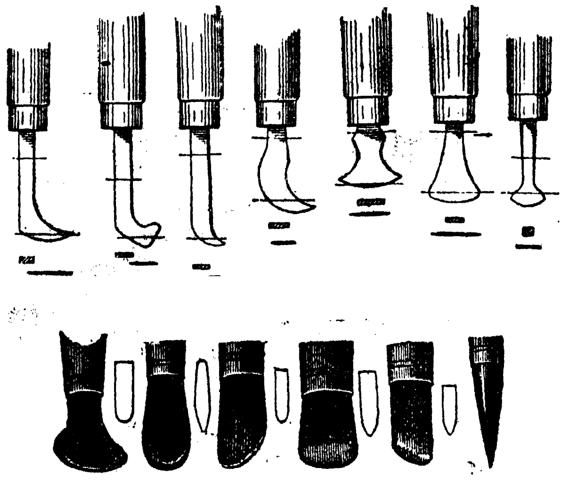
FIG. 42.



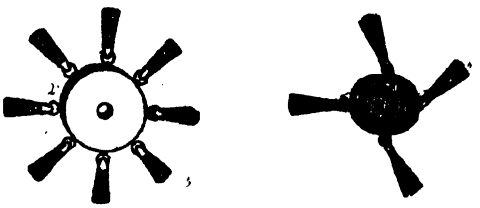
BURNISHERS.

brushed or scoured, and then handed over to women who use steel or agate burnishers of a variety of shapes (Fig. 42), to suit the different objects under treatment, the burnishers when melted on the surface break down the crystalline structure of the deposited metal. The surface thus obtained is streaky, and is therefore subjected to a further process of polishing known as colouring, which consists of rubbing down the surface over with rouge. This is either done by hand or on revolving swansdown mops. Spoons, forks, and such like articles, are usually rough burnished by men, then finished on calico mops with lime, and finally coloured with rouge. When the silver object is required to have a frosted or dead appearance, the articles are scratch brushed with a special construction of scratch brush, called swing brushes or hammers (Fig. 43), which have a beating action, and give a dead or matted appearance, or they are subjected to an impinging jet of fine sand, propelled by air pressure. Prior to the process of finishing, if the objects are hollow, they are usually dried out in hot boxwood sawdust.

Bright Silver Plating, which was the next discovery of importance, was due to an accident, and arose in the following way:—Messrs. Elkington and Co. used moulds for making silver electrotypes, composed of a mixture of wax and resin, the surface of the mould, for the purpose of electrical conduction, being covered with a film of phosphorus by means of a solution of phosphorous in bisulphide of carbon. These moulds were put in a cyanide silver-plating vat, together with other work, and it was observed that many of the articles came out bright, or partly so, and this led them to add bisulphide of carbon to the plating vat, with the result that, after some experimenting, good, bright deposits of silver could be obtained, instead of the frosted white deposits which are usual. A patent was eventually taken out in the joint names of Millwood and Lyons.

Bright plating, although useful for some purposes, is not employed so extensively as it was originally anticipated it would be, the solution being somewhat difficult to manage, even when in skilful hands. The appearance of bright plating is also very inferior to burnished or finished work, and does not keep its lustre for so long. It is chiefly used for very

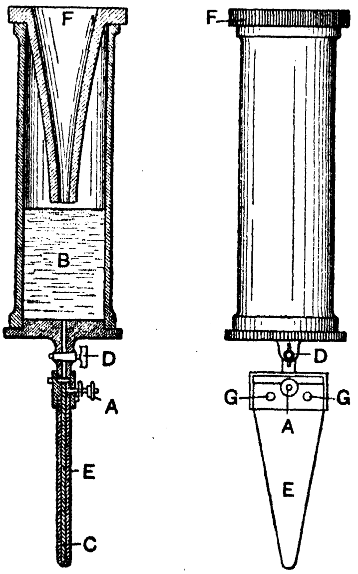
FIG. 43.



SWING BRUSHES OR HAMMERS FOR FROSTING.

cheap electro-plate, which merely requires to be coloured with silver so as to give it a finished appearance. It is also employed for coating articles with deep hollows, which are required to be bright, and could only be burnished with great difficulty. According to an analysis made by Gore, bright silver plate contains sulphur.

FIG. 44.



RESERVOIR DOCTOR.

Differential or Localised Electro-plating.—It is often desirable to partially coat one metal with another by electro-deposition, and occasions arise when it is not possible nor desirable to place the whole of an article in a plating bath. In such cases coating the article locally by electo-deposition is resorted to, and is commonly called "doctoring" or "ragging," and is accomplished in the following manner:—The work to be doctored is connected with the negative wire of the battery or dynamo, and a small piece of the metal to

FIG. 45.

be deposited is wrapped in some soft absorbent material such as swansdown, and is connected with the positive wire. The anode thus prepared is dipped in the plating solution and moved over that portion of the article which it is desired to plate for a minute or two, this operation being repeated. The process of ragging is employed for two purposes—for

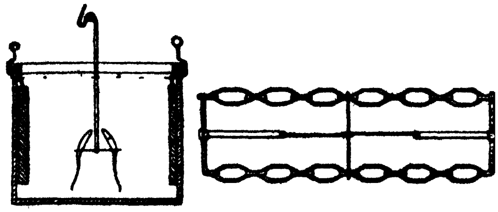
doctoring or patching up the electro-deposited metal on an article when it has been removed by some accident, or by careless work in the final operations of polishing and finishing, or for coating portions of articles which have been previously plated and then riveted or soldered up. Fig. 44 shows a doctor that is always ready for use. The plating solution is contained in a reservoir, which forms the handle, the speed of flow being regulated by a cock. The reservoir is kept supplied with the plating solution by means of a flexible tube connected to a tank placed a few feet above the operator. When necessary, the anode and its envelope can readily be replaced by loosening two set screws The doctor is held in the right hand and passed slowly over the surface to be coated. Fig. 45 shows the detailed construction of such a piece of apparatus A doctor in use attached to a rheostat for the regulating of the current density is shown in Fig. 46.

FIG. 46.

DOCTOR IN USE.

Fig. 47 shows Buck's apparatus for insuring a deposit of silver of varying thickness upon spoons, forks, or like articles, which are subjected to more wear upon one side than upon the other. The bath is arranged with two anode planes, and the articles to be plated are suspended in two planes, interior to the anode planes, with their surfaces outwards, upon which it is desired that the heaviest deposit of metal shall be produced.

FIG. 47.



BUCK'S APPARATUS FOR VARYING THICKNESS OF DEPOSIT.

A vat for plating spoons, forks, and similar articles is used in which the thickness of silver is distributed according to the wear on the different parts. After the

articles have been adjusted in the rocking bar, the flow of the plating solution is regulated into or out of the vat by some such arrangement as shown in Fig. 48, when the level of the electrolyte is gradually lowered by means of an adjustable syphon, in order to prevent the formation of a line of demarcation between sary inclination is by means of set screws placed at the side of the vat. In some cases it is advantageous to arrange for the automatic reduction of the current as the cathode area diminishes. The anode is preferably placed in a horizontal position near the bottom of the bath.

FIG. 48.

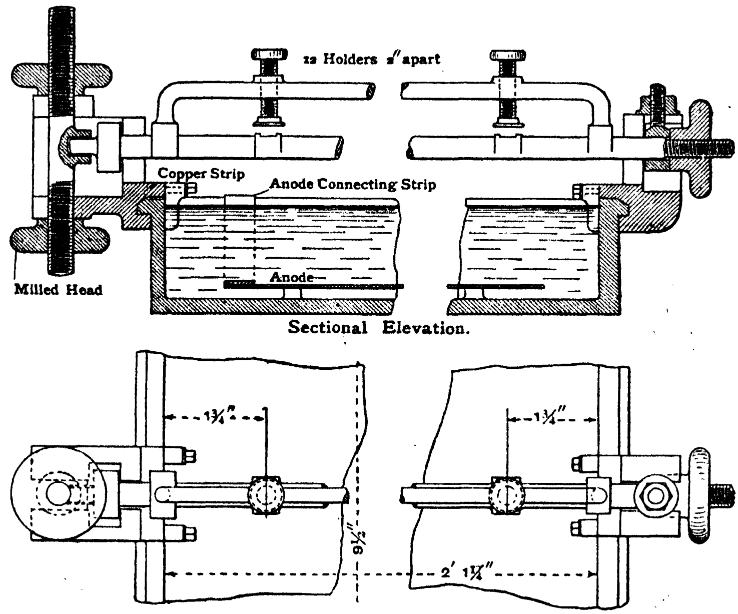


FIG. 49.

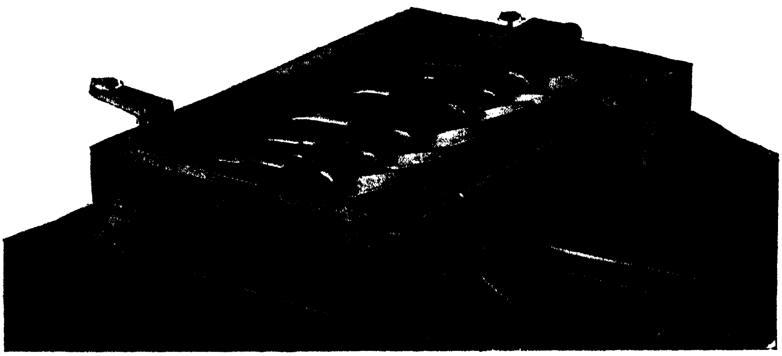


APPARATUS FOR THE DIFFERENTIAL PLATING.

the thick and thin portions of the deposited metal, so that the cost of polishing and finishing shall be no greater than is the case with articles plated in the ordinary way. The electrolyte should be freely agitated, so as to prevent the accumulation of any free cyanide of potassium on the top of the solution. The adjustment for giving the articles the neces-

Some manufacturers solder silver tips to the ends of the prongs of their best quality forks, but this only partially remedies the evil, as there are other portions of the fork which receive excessive wear. In America spoons and forks are manufactured with sterling silver let into those parts which receive most wear, the points of rest, or contact or wearing are

inlaid with standard silver, the whole being ultimately electro-plated.

All who use electro-plate will have noticed that the silver coat becomes entirely removed from those parts that receive most wear,

FIG. 50.

GENERAL ARRANGEMENT OF A PLATING SHOP.

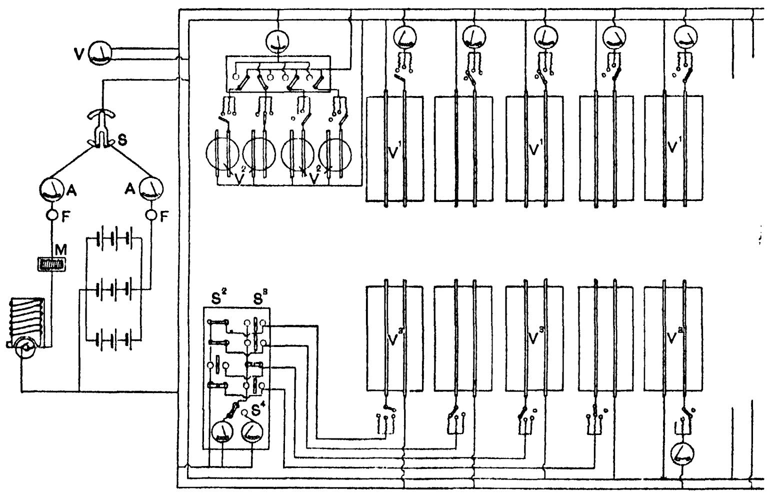
whilst the remainder of the plating remains almost as good as when new. It has doubtless occurred to many that if the coating metal could be distributed during the process of electro-deposition in such a manner that the wearing parts received a very thick coat and the non-wearing parts a comparatively thin coat, silver-plated articles could be produced which would wear two or three times as long as similar articles coated with the same weight of silver, the silvering being evenly distributed over the whole surface, or, expressed in other words, about half the weight of silver only would be required to produce articles having equal wearing properties.

Rudholzner, for the purpose of enabling the thickness of the deposit to be varied at will, arranges in the bath between the article and the anode, freely suspended plates of insulating material, provided with larger or smaller apertures. By this means, the parts of the article which are directly opposite the apertures, receive a thicker coating of metal than those parts which are protected more or less from the direct action of the current by the insulating plates.

Fig. 50 shows the general arrangement of a plating shop, with the scouring trough, the caustic soda cleansing solution, next to which is placed the tank containing the hot sawdust for drying hollow articles. Then there is the striking vat, and the tank of clean water in which the articles are swilled, so as to prevent the loss of the silver solution adhering to the articles. At the end of the shop are shown two scratch brush lathes.

Fig. 51 shows the general electrical and switch-board arrangement of a plating shop, the tanks being worked in parallel, matters being so arranged that when the dynamo is not running the accumulators can be switched into circuit to take its place, and Fig. 52 shows the general arrangement of a small plating shop.

FIG. 51.



GENERAL ELECTRICAL ARRANGEMENT OF PLATING SHOP.

The Electro-disposition of Silver Alloys.—Silver, which is the metal most largely deposited for ornamental purposes, is open to the objection of costliness and softness. It is well known what a marked effect a slight admix-

ture of some element when added to a pure metal, will make in its characteristics. It may be safely surmised that if by some such slight admixture, an alloy would be produced by electrolysis, having the appearance of pure silver, with the additional advantages of hardness and resistance to tarnishing influences, the discovery would possess an indisputable value. The chief work that has been done in this direction is with alloys of cadmium and silver, which have been successfully deposited on a commercial scale. The process consists of casting anodes of the same composition as the alloy to be deposited. An alloy of 30 per cent. of cadmium and 70 per cent. silver when rolled, develops a remarkable crystalline formation, breaking up into a series of triangular strips as shown in Fig. 53. If it is desired to deposit an alloy of this composition, cast anodes must be used, not rolled. The electrolyte is composed of the double cyanides of potassium and silver and cadmium. The relative proportions of the two metals in the solution cannot be based upon their electro-chemical equivalents, as a number of other important factors control the composition of the alloy deposited.

FIG. 52.

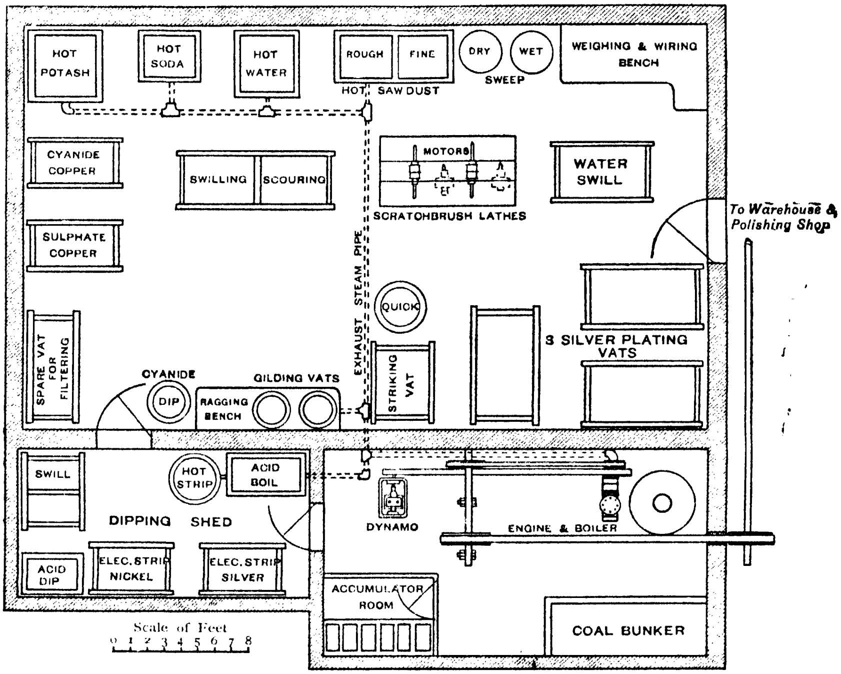


FIG. 53.

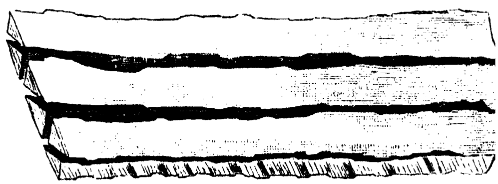

The results of many hundreds of experiments, show that the minor differences between the two metals, play a very important part; there is an electro-motive force between the two metals, independent of the electro-motive force of the cell; further, the current that will deposit 40·248 grammes of silver, will only deposit 2·076 cadmium, whilst there are considerable differences between the resistance of their respective salts in solution.

If an electrolyte be made up, containing a certain number of ounces of metal per gallon, and deposits be obtained at various current densities, the percentage of silver contained in the alloys will be different in every case, and different for every composition of solution, consequently it is only after much time and trouble and careful experiment, that the laws connecting the percentage of the alloys deposited, composition and density of solution and current density can be obtained. The

foregoing remarks readily indicate the laws governing the deposit of silver and cadmium.

A solution, whose metal contents are two or three ounces per gallon, and which contains a large amount of cadmium, gives at very small current densities, which alone are practical on account of the smoothness of deposit required, deposits varying from 40 per cent. to 100 per cent. of silver, whereas a solution containing eight or nine ounces of metal to the gallon, gives 80 per cent. or 90 per cent. of silver for a very large range of current density.

For any given solution, the percentage of the more positive metal increases with the current density, but the variation is not one of simple proportions. If the solution be a weak one, patchy deposits are the result of using too high current density, and the metals are not deposited as a true alloy. The relation between the percentage of the electro-negative metal and the electro-positive metal at a given current density, can be varied by agitating the solution or moving the electrodes. If the bath is weak in metal and the anodes are not dissolving freely, the resistance will be altered, consequently the current density and the nature and composition of the alloy will vary. In short, it may be said that for every composition and density of solution, there is a different current density required to give a definite composition and alloy, and if the electrolyte is to be maintained for any length of time in working condition, the deposit must have the same composition as the anode. In order to check the working of the bath, small platinum test pieces should be employed, so that the composition of the deposit can be readily ascertained.

During the last few years numerous investigations have been carried out, with the object of determining whether there are any other practical methods of rendering silver less tarnishable. Amongst the series of experiments that have been made may be mentioned the deposition by simple immersion, the electro-deposition of various metals such as tin, zinc, cadmium, chromium, on the silver surface to be rendered less tarnishable, which was then baked in hot air or high melting point waxes, so as to cause the silver to absorb the thin film of deposited metal. Another series of experiments consisted of subjecting the silver coated with the metals above referred to, to pressure under various conditions, also electro-depositing on the silver surface under pressure. A fourth series of experiments consisted of making various amalgams and applying these to the silver surface, and then driving off the mercury by heat.

Some of these methods have given promising results in the laboratory, but when put to a practical test, were found unreliable. One of the chief difficulties encountered was the retaining of the true colour of the silver, and, at the same time, alloying the silver sufficiently deep to ensure it withstanding the final polishing and finishing operations, there being a tendency to penetrate the alloy on the edges, and most prominent portions.

On the table will be found some specimens of silver-cadmium alloys deposited in various percentages, also ornamental electro-silver objects, rendered non-tarnishable by a new process of hard lacquering, which ensures a very hard, even coating in intimate contact with the underlying silver.

CONCLUSION.

Electro-plate, from an economist's point of view, offers many advantages over Sheffield plating, as the metal of which the electro-plated objects are made is much harder than the copper used for Sheffield plate, and is, therefore, less liable to be bruised and dented. On the other hand, silver electro-deposited is softer than the silver rolled on by the Sheffield process. When the silver becomes worn off in places in electro-plate, the contrast of colour between the copper nickel alloy and the silver is not so pronounced as between the copper and the silver in Sheffield plate. The joints in electro-plate are hard soldered not soft soldered as in the case of Sheffield plate, and the thickness of silver in electro-plate can be more easily distributed so as to be thicker in those portions that receive most wear.

It is to be hoped that England, which was the birthplace of Sheffield and electro-plate, will continue to take the lead in this important industry. Although the art of electro-plating has been brought to considerable perfection, there remains much to be done, and it is a fruitful field of investigation for the electro-chemist. Electro-plating in many large establishments is still carried on by rule of thumb, with much waste of material and the production of an unnecessarily large percentage of faulty articles which require to be replated or doctored. It is to be hoped that before long all such works will be managed on truly scientific lines, with resulting economies. Research work must be systematically carried out to bring about those improvements

and developments in the industry undoubtedly will be evolved before long. Electrochemistry is taking an important place in almost every branch of industry, and electrochemists now have their own society, the Faraday Society, established for the purpose of promoting the study of electro-chemistry and electro-metallurgy. Many problems remain to be solved in connection with the silver electro-plating industry alone, some of which have already been referred to, and it is to be hoped that the birthplace of this important industry will be the first to bring any important improvements to a practical issue.

In conclusion, I should like to thank the authorities at South Kensington for the loan of the fine specimens of Sheffield plate exhibited here to-night, and also the Chairman, Sir John Bingham, for the beautiful specimens of electro-plate, which are particularly interesting as the mouldings are stamped from the same dies originally used for making Sheffield plate, the only difference being that in the former case they were stamped in thin silver, instead of a copper nickel alloy, and then coated with silver by electro-deposition.

DISCUSSION.

The CHAIRMAN, in opening the discussion, remarked that the essence of success in competitive undertakings was the method in which manufacturers conducted their business. He did not believe that the author had been over his (the Chairman's) works at Sheffield, and he would be delighted if not only that gentleman but the whole of that scientific audience would take the opportunity of inspecting the two miles of benching at his works, because if they would only come and see the actual processes of manufacture they would gain a much greater amount of information than could be given in any lecture or speech. Dr. Wright, of Attercliffe, and his (the Chairman's) late revered partner, George Walker, really discovered electro-plating, but the first conception of the idea was Dr. Wright's, to whom the whole of the honour in that connection was due. It was in his opinion only proper that Sheffield should have the honour of the discovery of electro-plating, because it had eventuated in a very great business indeed in which many tons of silver were annually deposited. The author had stated that the difference between electro-plate and old Sheffield plate was that the one, I believe, had less silver upon it than the other. That entirely depended upon how much silver was put upon the Sheffield plate, because electro-plate could beat old Sheffield plate if the customers would only go to the expense of the necessary silver. The base or under part, nickel silver, if made by a good house should be quite white, and almost impossible of detection when the silver had been worn through. A really good house would use silver solder, but common houses used a darker coloured nickel which wore through yellow, and they also used soft solder which was liable to go to pieces, as it often did, and had sometimes given electro-plate a bad name. The best quality electro-plate was a great deal more valuable than light sterling silver goods, and although it cost only about one-third the price would wear much longer. He did not desire to run down silver goods, because he made many tons of them in a year, and was just as pleased when he received an order for silver as for electro-plated articles, but thin silver was of no use. Friends had frequently sent silver-backed hair brushes to him to have their names engraved on them, but it was impossible to do the engraving because the tool went through the silver in a moment owing to its thinness. He could support the evidence the author had given in the slides he had shown on the screen. The audience would remember there was one mark consisting of cross keys and H.W. That firm manufactured Sheffield plate for over a hundred years, and he (the Chairman) was fortunate enough to bid more than anyone else for their dies when they were sold. He had tons of those dies, and was only sorry that the taste of the present day did not sufficiently permit of their use. He was sorry more old Sheffield plate designs were not used. In its future manufacture he would suggest, however, that instead of being plated upon copper it should, on account of the colour, be plated upon nickel silver. He would have the greatest possible pleasure in sending to the whole of the audience a little pamphlet containing a number of pictures of his works and the processes conducted.

Mr. FIENNES DAVENPORT enquired whether the process of old Sheffield plating was ever performed upon a base of brass.

Mr. COWPER-COLES replied that, as far as he knew, the base was always copper. He believed the reason was that copper and silver had a great affinity, recent researches having shown that a low melting point alloy was obtained with those metals in contact. The silver probably gave off a vapour and combined with the copper; the two surfaces formed a low melting surface alloy, and made a union between the two. He believed manufacturers had not been successful in using brass.

The CHAIRMAN stated that manufacturers had not been successful in using brass for close plating purposes. The discoverer of close plating was a gentleman who wished to use some silver and copper soldered together, but he made the ingot too thick. Instead of filing it he took it to one of the old time Sheffield mills, which were very primitive undertakings then, where it was slightly rolled down. Looking at it

when he received it again, he was surprised to find that the silver and copper had rolled out about evenly; and being a man of thought he had it further rolled, with the result that it rolled down into a sheet. He also found that the sheet of silver, with the soft solder under it, and the copper under that, had all rolled down evenly. Brass was harder than copper, and copper and silver rolling as they did—just equivalently—were right for the purpose; but hard brass, compared with the softer copper, would not roll in the same proportion, and, therefore, would be useless for close plating.

Mr. T. T. GREIG remarked that he had always been under the impression, until hearing the paper, that the material for Sheffield plate could be obtained by the single process of rolling the silver on to the copper cold, as the Chairman had suggested; but, on the other hand, the author stated it was done between two ingots, heat being applied. Was it a fact that the Sheffield plate material could not be obtained without heat, or could it be rolled cold?

The CHAIRMAN replied that Mr. Greig was quite right and also quite wrong. If a sheet of silver and a sheet of copper were soldered together they rolled out equivalently when rolled cold, but in the first instance heat had to be applied to solder the silver to the copper.

Mr. GREIG inquired whether, with modern electroplating, if an article were used for a short time, but not by any means worn out, and then sent to the manufacturer to be electro-plated with a view of getting a richer and thicker coat of silver on it, it was necessary to rub or scratch off, as he understood the author to say, the old electro-plate before putting on the new coat. If that were so it would be no good sending an article two, three, or four times with a view to getting a richer and thicker coat of silver upon it.

The CHAIRMAN replied that a good deal of nonsense was talked about double, treble and quadruple plating. No one who had any brains would attempt to do it in the way the speaker had described; they would put the plating on all at once. In his works it was known to a nicety how much plating would be placed on an article in a vat with a given amount of electricity. It need not be sent several times to the works to be re-dipped. It was not at all necessary that the plating of silver should be taken off. If the plating was very much worn away in one part and the silver was thick in other parts, they sometimes took it off and put the whole coat on evenly again; but there was no necessity to do that providing the silver was put on firmly, which was now an easy thing to do. He remembered the time when the silver was put on very crudely, and when it had to be filed level, because the manufacturers did not know their business; and many a time it fell down in the vat as real silver sand and would not adhere at all. All those things had been done away with now. The article could be taken out of the vat ready for burnishing and finishing off; and if an article was sent to them with the request that a coat of silver should be put upon it, it was not necessary to disturb any plating which was already upon the article, it would be sent back to the owner finished, and he would not know it from a new piece of goods.

Mr. RATHBONE was under the impression that ordinary electro-plate ware was apt to blister if it was soldered when being repaired, but he imagined from what had been said about the preparation of old Sheffield plate that that danger would not exist in that class of article. He believed it was the custom in some kinds of solid silver ware to electro-plate the work before it was polished. If such an article had to be repaired at a later time, and he was right in thinking that an electro-plate deposit of silver was apt to blister under the blowpipe, that danger would exist. It seemed to him to be a great argument in favour of old Sheffield plate if it was free from such danger; but, perhaps, he was altogether wrong in his surmise.

The CHAIRMAN replied that Mr. Rathbone was altogether wrong. In old Sheffield plate the silver coating was practically soldered on to the copper base. If a close-plated knife was held in the gas or a candle, the silver would strip off in a sheet; if a wine-cooler was held against a flame the solder would bubble up underneath the silver ground; and the silver would strip off because the solder would melt. It was not the case that solid silver ware had silver deposited on it in the process of manufacture before polishing; but occasionally, when there was so-called fire in the process of manufacture which made the silver a shade streaky and red in parts, it was sometimes slipped into the vats to obliterate that fire. If it was properly done the article could then go into the market; if not, it had to be slightly brushed. If such an article was heated red-hot afterwards, it did not cause any blistering, in fact, the amount of silver which went on was infinitesimal.

Mr. RATHBONE asked how, if the solder which attached the silver to the copper in the old Sheffield plate melted so readily, it was annealed in the process of beating it up into shape.

The CHAIRMAN replied that that could not be done, otherwise the article would be blistered. Nickel silver was annealed many times, and silver was only annealed for convenience sake. Silver would not blister when deposited upon nickel silver; but silver being more easily melted than nickel silver, if electroplate was subjected to a great heat the silver would run.

Mr. HUGH STANNUS thought the paper would be most valuable as a work of reference, and that the members of the Society would read it with great interest when it appeared in the *Journal*. He had stated before, at a meeting, that he thought it would be a very desirable thing if some of the Sheffield manufacturers would take a leaf out of the book of their Japanese brethren in the manufacture of silver ware. The Japanese could teach Europeans a good many things in applied arts, as also in other directions. For instance, in their method of mixing alloys, while they had not exhausted its possibilities, they had undoubtedly shown all silver-workers the way to introduce a great deal of beauty of colour. Silver here was merely one bright colour, which was very pretty and dear to the British housewife; but every artist who had a liking for colour would prefer that his silver work should be oxidised and tarnished. He had a pair of very beautiful old silver candlesticks which were a magnificent bronzy kind of colour, but a British servant girl, armed with whitening, cleaned them, scratched them and spoilt their beauty. He thought a distinction might be made in silver articles between the portion which was put into the mouth and the portion which was handled. A difference was made in the case of the knife, there being a steel portion and an ivory portion; and he suggested that in a spoon one portion might be made of a Japanese alloy and the other of silver plate. The author when referring to the process of spinning had said it was confined to round objects, by which he meant objects which had a circle as their sectional area; but as a matter of fact it was a regular thing to spin objects which were elliptic in plan. When an object was round and it spun on the centre of motion, every portion of the circle being at the same distance from the centre, all that the workman did was to hold his wooden tool and push the plate of metal on to the solid matrix which gave the shape of the cup, basin or whatever the article was. If it were an ellipse, however, obviously as it was farther from the half-longer diameter than it was from the half-shorter diameter, the centre had to move backwards and forwards, and when the shorter diameter came against the tool the centre was closer; when the longer portion came against the tool the centre was moved back, and so it kept moving. He did not know whether that was an exclusive patent but he had often seen it carried into effect; every lady would know it as used in dish covers, which were elliptic in plan. He thought the members were very much indebted to the author for his thoughtful and exhaustive paper, and sympathetically agreed with his suggestions that more science should be applied in the manufacture of silver objects. If it paid a brewer to keep a trained chemist, surely it would pay a silver plater to do so; and he quite expected to hear that the Chairman in his great factory at Sheffield had a trained chemist to help in the supervision of the electro deposit. The Chairman, by his remarks and the explanations he had given, had materially added to the interest of the paper, and laid the audience under an obligation.

Mr. W. M. MORDEY remarked that the author was one of the hardest workers on electro-metallurgical subjects, and combined in a singular degree a knowledge of the scientific side of the subject with a knowledge of and sympathy with the artistic side. Mr. Cowper-Coles had produced more than one admirable new process in metal work and in the application of science to artistic work in metals, and he was sure all had learned a great deal by listening to his paper on such an interesting subject. As an electrical engineer, he (Mr. Mordey) desired to support the suggestion that more science should be put into the manufacturing process of electro-plating. He had not had the pleasure and privilege of going over the Chairman's works, but he had been through other large electro-plating works, and he had been surprised at the crudeness of the electrical applications, although he could not but admire the excellent results that were obtained. He desired to ask the author to state in his reply whether much so-called old Sheffield plate was now being made—a good deal of it was seen on the market. It was rather a curious thing when one thought of it that old Sheffield plate really began by being a sham; it was covering up a base metal with a nobler metal. It showed what a curious thing fashion was, because people now prized the old Sheffield plate more if they could see the base metal underneath—actually prized it for the very object that people strove to hide when the method was first introduced. Personally he had been expecting and hoping that more objects of ordinary use would be made of solid silver, as silver, at the present time, being little more than two shillings an ounce, was very much cheaper than in the days when electro-plating was first introduced. That process, however, was not at all likely to disappear.

Mr. COWPER-COLES, in reply to Mr. Mordey's question with regard to the manufacture of old Sheffield plate, said he was told that a large quantity was being manufactured at the present time on the Continent and in Denmark. Copper articles were made and then electro-plated, some of the silver being rubbed off from small portions in order to make them look like old Sheffield plate. There were a great number of those articles now on the London market, and it was only by careful examination that one was able to detect the fraud. He thanked the audience very much for the kind way in which his paper had been received, and also the Chairman for specially coming up from Sheffield to preside. His practical knowledge in connection with old Sheffield plate and electro-plating had been of the greatest benefit to all.

The CHAIRMAN, in proposing a vote of thanks to Mr. Cowper-Coles, reiterated his invitation to the members to visit his works at Sheffield, where he

would be only too delighted to show them all the processes described in the paper. The remark had been made that old Sheffield plate was a sham, but it had also been beneficial because it had prevented a good deal of thievery. A learned judge once said that one of the benefits that electro plating had given to mankind was that it had saved a great many people from crime. He had seen specimens of electro-plating which had lasted over forty-five years. He did not think such articles could be called a fraud, and the purchaser of them could not have been taken in much. He was quite sure that the present light silver articles would not wear a quarter of the time that good electro-plate would.

THE PRODUCTION OF GRAIN AND FLOUR IN MANCHURIA.

Although an immense stream of Chinese immigration has flowed into North Manchuria from the south during the last ten years, only narrow borders along the rivers and routes of travel have been settled. Vast districts in the north and west yet remain only partially explored. The chief occupation of the settlers is agriculture. The valleys of the Sungari, the Mutan Chiang, and the Nonni rivers, together with the bordering plains of North-Eastern Mongolia, comprising an approximate area of 70,000 or 80,000 square miles, possess a soil and climate especially suited to the production of wheat and other grains. The agricultural possibilities of these districts have scarcely been touched. At the beginning of the construction of the Eastern Chinese Railway, ten years ago, the Chinese population in all North Manchuria did not number 1,500,000, and was chiefly centred around Kwanchengtze, Kirin, Petuna, Sansing Ninguta, Tsitsihar, and a few other small centres, The American Consul at Harbin says that the principal agricultural products were "kao-liang," or tall millet, "hsiao-mi," or Italian millet, "huang-mi," or the common German variety of millet, wheat, dry-ground rice, barley, maize, and buckwheat. The surplus of these products was transported by cart to the south during the winter, when the ground and streams were frozen, and carting was easy. Upon the arrival of the construction forces of the railway, and later the military forces, there was a large demand for grain and flour which it was necessary to supply from abroad, and which on account of the inconvenient transportation facilities, was very expensive. The surplus production of wheat in North Manchuria at that time did not amount to more than 500,000 bushels a year. In order to supply the sudden demand the Chinese were ordered by the military authorities, under pain of punishment, to sell their grain to the supply departments of the Russian army and the railway. This caused a temporary check in the production, but the steadily increasing demand forced up the prices, especially of wheat. As the demand was the greatest for wheat, the production of that grain took the lead. The production of grain in North Manchuria in 1905, as estimated by the Chinese brokers in Harbin, in bushels, was as follows:—Wheat, 21,000,000; kao-liang, 12,000,000; beans, 12,000,000; both varieties of small millet, 13,000,000; barley, 6,000,000; oats, 900,000; and rice, maize and other grains, 6,500,000. Of the total production of 21,000,000 bushels of wheat, 13,500,000 bushels were marketed, the balance having been retained in the districts for consumption and seed. Owing to the severe winters and the light snowfall, so that no protection is afforded against frost, winter wheat is not grown in North Manchuria. The Chinese farmer usually plants only such areas as he can attend to himself, seldom employing help. The ground is prepared as soon as it thaws in spring. The surface is well worked, but deep ploughing is not practised. The grain is planted in rows, about ten inches apart. The weeds are kept out, and the surface of the ground is usually stirred twice during the growing season. Only the simplest kinds of ploughs and other farming implements are used. The harvesting is done by hand, and the wheat in the head is stacked for threshing, during the winter, on the frozen ground. The average yield is from seventeen to twenty-five bushels per acre. The grain is threshed out by stone rollers, and by treading. As farming mills are not generally used, the grain when brought to market is usually very dirty, containing from fifteen to twenty per cent. of foreign matter. As the threshing is a winter occupation, the new grain does not come upon the market until late, and after the navigation on the rivers is closed. The smaller farmers send their grain to Harbin or other markets by carts, from distances of from sixty to two hundred miles. On account of the high rates of transport, very small quantities of grain are transported to Harbin by rail. The flour milling industry of North Manchuria is an outgrowth of Russia's railway extension and military occupation of Manchuria. These two branches have been the main sources of the demand for this flour. By the withdrawal of the army, the industry received a sudden and severe check. Before 1900, there was not a modern flour mill in North Manchuria. The large demand for flour from the army and railway which developed at that time was supplied from abroad, chiefly from America. In order to obtain a cheaper article, and at the same time to develop Russian industries, the Russian authorities encouraged the erection of flour mills. In August, 1906, at the time of the withdrawal of the main forces of the Russian army, there were in Harbin twelve mills, with a total daily capacity of 6,000 barrels, and since then one of these mills has completed extensions which give it an additional daily capacity of 2,000 barrels. In addition to these there are eight mills in other parts of North Manchuria having an aggregate daily capacity of 3,000 barrels per day. While several of these mills are equipped with obsolete machinery, the plants more recently put up are quite modern and of perfected type. For instance, the

Sungari mills, which have a capacity of 3,000 barrels daily, are equipped with electric power and the latest improved German machinery. Unfortunately for the industry nearly all these flour mills have been built with borrowed capital, on which extremely high rates of interest have been paid. One of these mills which was indebted, on account of advances and other obligations, to the extent of nearly £81,000, was recently bought up by the Russo-Chinese Bank for £10,000. Recently the four largest flour milling companies in North Manchuria, the Sungari Company, the Zozulinsky Company, the Kavalsky Company, and the Myakoff Company, controlling the six largest mills, formed a combine and sent representatives to St. Petersburg to secure additional capital with which to liquidate their obligations, increase their capacities, and carry on their operations. About £516,000 was secured. The combined capacity of these mills at present is nearly 7,000 barrels of flour daily. This is to be increased to 10,000 barrels in the near future. It is the intention of the proposed combine to control the flour markets of North Manchuria and Siberia, and also to enter the markets of Japan and China. In order to encourage the combine the Eastern Chinese Railway Company has made a special rate for Manchurian flour from Harbin to Vladivostok, on condition that it is for export. A few of the smaller mills have declined to enter the combine at the present time, partly on account of the doubts they entertain as to the ultimate success of the undertaking, and partly for the reason that they consider that the larger mills cannot be worked as economically as their own. A noticeable feature in connection with the flour mills of North Manchuria is, that while some of the first mills put up are equipped with American machinery, nearly all the machinery recently installed is of German make. This is the result of the German makers having a branch at Moscow, whose representatives made periodical visits to Harbin, and keep in close touch with the flour milling interests there. The chief obstacles that appear to be in the way of Manchurian flour competing successfully with other flour in the outside markets are: (1) the primitive and wasteful methods of the Chinese farmers in the cultivation of wheat, and (2) the high cost of transportation of the flour. The farmers more than lose the advantage that their cheap labour gives them by not employing modern implements and machinery, not properly working the soil, and not cultivating improved varieties of grain. Their custom has been to sell the best and save the poorest grain for seed. An examination of the wheat as it comes to market, shows that several varieties are cultivated together, some of which are almost worthless, and greatly reduce the percentage of flour obtained, as well as the yield of grain from the land. However, in view of the closer attention that the Chinese authorities are commencing to give to the development of the economical resources of North Manchuria, it is probable that these unfavourable conditions will be gradually removed. The Consul says that the Manchurian field offers fair opportunities to any large farming implement and machinery makers who would undertake to develop a market in Manchuria by establishing an agency, either at Harbin or Kwanchengtze, with branches in the principal agricultural centres, where they could demonstrate to the farmers the advantages of modern implements. The Japanese and German manufacturers are already finding markets for cheap ploughs and other implements. It will be of little avail for manufacturers to attempt to sell their goods from catalogues or through correspondence, especially in the English language, when the Japanese and German manufacturers have active representatives in the field. The Chinese wish to see the goods and understand how they work before buying. In conclusion, the Consul says that if manufacturers wish to secure markets in Manchuria, and hold them, they should go there and sell their own goods, and not trust to houses there that have no special interests in their affairs to represent them.

COTTON-GROWING IN QUEENSLAND.

The great importance, from the national point of view, of increasing the area of cotton cultivation within the British Empire is now generally recognised, and much useful work has been done in this direction, more especially by the British Cotton Growing Association. The difficulties in the way of rapid development of cultivation are many, and perhaps the greatest of all is labour. There are many parts of the world where climate and soil are suitable to the growth of cotton, but few where labour is sufficiently plentiful, efficient, and cheap to make it a commercial success. It is this fact which has given the Southern States of America the predominant position they hold as cotton producers. They have the finest supply of cheap labour in the world. At the time of emancipation it was feared that the cotton industry would be ruined from the want of labour, that the free negro in the Southern States would become an intermittent worker only, as in the West Indies and elsewhere. That fear has not been realised. Whatever his faults the negro of the Southern States is a splendid worker, and he is content with a low wage. In no other country is there such a magnificent supply of labour suitable for the cotton field. But the peril of depending mainly upon the Southern States for the cotton requirements of Lancashire becomes greater every year. At the time of emancipation Great Britain took the great bulk of the cotton grown. But since then, and more especially of late years, the American home demand has increased enormously, and, concurrently, the requirements of the continent of Europe, not to speak of the United Kingdom, have grown rapidly. On the other hand, whilst the area of cultivation in the Southern States has increased, the increase has not been in proportion to the growth of the demand, and

although the exports from Egypt, India, and elsewhere have increased, the world's dependence upon the Southern States does not lessen. The danger to the United Kingdom of this state of things has only recently led to a serious and organised attempt on the part of Lancashire to improve the position by encouraging the growth of cotton within the British Empire. This growth is necessarily slow, but there are grounds for hope that at no very distant date Lancashire will draw much of her cotton supply from Greater Britain. The recent history of tea cultivation shows what can be done in this direction. Within the memory of men not yet very old practically the whole of the tea consumed by the people of the United Kingdon came from China. To-day the supply from that source is insignificant. Almost the whole of the tea consumed is from India and Ceylon, that is to say from within the British Empire. What has been done with tea may conceivably be done with cotton.

Of all the dependencies of the Empire there would seem to be none more suitable for cotton growing than Australia. Seven-eighths of the Australian continent, or 2,576,362 square miles, is within the latitude south of the equator, which might be devoted to the cultivation of cotton. The best qualities cotton can be grown in the Northern Territory of South Australia, Queensland, and New South Wales in unlimited quantities; but the population is scanty. In the Northern Territory, with its 335,116,800 acres, there are only about 900 whites and 2,700 Chinese, in addition to the aboriginal population. So suitable are the climate and soil for the growth of cotton, that it has disseminated itself without the help of man, and may almost be considered as part of the North Australian flora. Of the eight species of cotton, seven varieties are found in the Northern Territory. The harvest of the ripe product falls almost wholly in the dry season, so that the picking is little interrupted by rain, which in the Southern States of America not infrequently spoils much of the crop. The annual cultivation of cotton is a problem requiring for its solution chemical and botanical knowledge in addition to practical experience. The present commanding position of the Southern States of America in cotton cultivation is largely due to its well-organised and splendidly-equipped experiment stations, conducted by the Department of Agriculture, and constantly engaged in scientific investigations into the many problems which arise, and in the collection and dissemination of information. It may be hoped that the South Australian Government will see its way to act upon Mr. John Bottomley's advice to establish an experimental station, and a seed farm where agricultural experiments in cotton may be carried out, and where selected seed may be grown for distribution to cultivators.

The question of the labour supply is the crucial one in Australia, as elsewhere, but it would seem as if the problem can be solved in Queensland. Reporting on cotton cultivation in that State, under date April, 1904, Mr. Bottomley, who as an expert on cotton cultivation is an admitted authority, wrote, "Given authority to offer on behalf of the Cotton Growing Association, say 1¾d. per lb., as a minimum price during the coming three seasons, we were assured that large areas of land now under maize would revert once more to cotton, and a large export trade to Lancashire would result without any probability of cessation even if prices lowered somewhat. With added experience, and improved varieties, cotton can, we are sure, be grown in Queensland cheaper than in any country in the world." It is a little surprising that, so far as Queensland is concerned, the Association has not acted upon this suggestion of its own reporter. In Mr. Bottomley's opinion, "Queensland is well suited for the immediate settlement of thousands of cotton growers who, in a short time, can make a good living from the industry." Mr. Bottomley puts the cost of production, including packing and every expense of tillage, and transit from plantation or farm to seaport at from £3 to £4 per acre, allowing for labour, on the basis of white wages. With yields of raw cotton, ranging from 1,000 to 1,600 lbs. per acre, this should pay. As to labour, there would seem to be a fair supply of "odd job" men who are not unwilling to take up light work, such as cotton picking at a moderate wage. Mr. Bottomley's estimate of cost would seem to be borne out by Mr. Daniel Jones, of the Queensland Agricultural Department, who recently put the cost of cultivation of an acre of cotton at £3 16s. 2d., made up as follows:—Two ploughings, 17s.; two harrowings, 2s.; drilling and sowing, 1s. 6d.; three scufflings, 4s. 6d.; thinning and hoeing, 3s.; carriage, 5s.; seed, 1s. 6d.; picking, ½d. per lb. (£2 1s. 8d.); total, £3 16s. 2d. The yield was put by Mr. Jones at 1,000 lbs. at 1½d., which would give £6 5s., and leave a profit of £2 8s. 10d. Assuming this estimate to be near the mark (it seems a moderate one) it will be seen that the profit is only small, since nothing appears to be allowed for rent, but it would probably be sufficient, if only it could be relied upon, and there was certainty of a market, to induce a considerable area of cultivation.

ORIENTAL CARPETS.

The carpet industry is in a very flourishing condition both in Persia and in Asia Minor. The market value of the carpets may be the same in the two countries, yet a great difference exists in the way they are made. This applies not only to the various shapes and lines, but to the grouping of forms and colours as well, which enables everyone unskilled in the business to distinguish between the make of Smyrna and that of Tabriz. The article which is sold in the world's markets as the celebrated Smyrna carpet is not made in Smyrna; it is a product of the vilayet of Aidin, of which Smyrna is the capital. According to a recent report by the American Consul at Smyrna, the chief places of manufacture are the villages of Uschak,

Koule, Ghiardis, Makri, Malessos, Kirkagatsch, Axar, and Demirdji. The production of carpets in Asia Minor is essentially a home industry, and the natives are exceedingly skilful in their handiwork. The industry gives employment and a means of livelihood to thousands of needy people, especially women, who are obliged to do the work almost entirely, while the men spend their time in the coffee houses, drinking strong coffee and smoking numberless cigarettes, all in true Oriental fashion. Little girls are compelled to take up the work early, at 7 or 10 years of age at the latest, and they keep to it unceasingly all their lives. Some efforts have recently been made to introduce the carpet factory system into Smyrna, which have, however, been attended with indifferent success. Labour is dearer in Smyrna than it is in the country districts, and the girls and women must pay more for food and lodging in that city than in the country villages. Many claim that the work done on the looms at Smyrna is more exact in measurement and neater in appearance for the reason that the manufacturer or merchant is able to superintend the operations at any time of the day, thus preventing mistakes which might prove fatal to some beautiful design. The looms set up in Smyrna, and worked by some sixty girls, number twenty. On the whole the experiment does not seem to be a success, and the number is not increasing. Uschak carpets are made in two styles. They are made either of spun wool or long wool, those of the former costing from 4s. 1d. to 6s. 9d. per square yard, the latter 10s. 2d. to 20s. 6d., according to the design and colour, and the size of the carpet. The web and the woof of the Uschak carpets are made of the wool of the fat-tailed sheep. The men wash this wool in the rivers, and the women comb and twist it softly in such a way as to allow the threads of different colours to blend lightly on the edges, in the same way as the different tones of a picture. The market for the wools, which have been thus spun and coloured ready for the carpet weavers, is held every Thursday, from dawn to sunset, in the bazaar of Uschak, which is then filled with purchasers, who have arrived on buffaloes, camels, donkeys, and other beasts of burden. The spun wools are not dyed by the weavers themselves, but by special dyers. For a short time artificial dyes were used, but their use was soon abandoned in favour of the better taste displayed by the admirers of Oriental carpets, who desired the ancient models and colours, thus reviving the use of vegetable colours extracted from madder, yellow berry, and valonia, and other products of the country, and from indigo brought by caravans. More than three thousand female weavers are employed at Uschak in the preparation of carpets. The looms are set up in about one thousand houses. The workers in each house are generally members of the same family, but there are, in addition, a number of girls employed, who earn about sixpence a day. The Ghiardis carpets are generally smaller than those of Uschak. Very fine prayer carpets, closely woven, and of harmonious colours, are produced in imitation of the Persian carpets. The dimensions of these carpets average five to seven feet by three feet ten inches. The weavers of Koule and Ghiardis use wool of a superior quality to that of the Uschak weavers for the woof, while the web is made of hemp. Large carpets as well as prayer rugs are made in Koule. In the village of Demirdji the carpet industry was for some time neglected, but ancient Oriental models having again come into fashion, the industry has improved, and the district now produces a very fine carpet, thick and closely woven, soft, and very strong. The web is of cotton. It is estimated that the three centres of carpet manufacture of Ghiardis, Koule, and Demirdji produce more carpets than the Uschak. Their prices are also a little higher, for they sell at not less than thirteen shillings and sixpence to twenty shillings and sixpence the square yard, the superior qualities at from forty shillings and ninepence to sixty-eight shillings per yard, and for certain old carpets which have become very rare the prices are exorbitant. The annual production of these carpets is estimated at 440,500 square yards, worth £280,000. The carpets are made into bales of 280 pounds each, and covered with goat skins. The caravans pass the night in the open country at the foot of some hill, the drivers under tents, and the camels and their loads in the open air. Very large carpets, too heavy to be packed, are folded and thrown across the backs of the camels in the form of a covering. When the carpets arrive in Smyrna they are spread out, beaten, brushed, and repacked in bales, weighing from five hundred to six hundred pounds each, for exportation to different parts of the world.

HONITON LACE-MAKING IN DEVON.

The revival of lace-making in Devon has just been reported upon by the Lace Committee of the Devon Education Authority as being very satisfactory in the adult classes held at Honiton, a large number of people having visited the town in order to see the lace, and, at the instance of Lady Northcote, a recommendation was made that an exhibit of lace made at these classes should be sent to the forthcoming Australian Exhibition. Lace-making is one of the crafts included in the scheme of the Higher Education Committee for the county, and some time since an instructress was appointed to superintend the classes that might be formed in the county, but the difficulty has been that local committees in small centres have been unable to obtain the necessary services for teaching. The report acknowledges that more teachers are wanted, but owing to expense they cannot be supplied It is anckowledged that a great advance has been made in the industry during the last two or three years, and it is unfortunate that the revival and development of such an interesting and profitable occupation for our female rural population should be crippled for the want of funds.

HOME INDUSTRIES.

Cloth Hearth-rug Factories. — Reporting upon industrial changes and developments, Miss Slocock, one of the lady inspectors of factories and worshops, says she had the novel experience in Huddersfield of inspecting a trade which was dying for want of workers. She visited the cloth hearth-rug factories and workshops, and heard the same complaint everywhere—that it was impossible to get workers. It is rough, heavy work, and the trade has got a bad name in the town, so the respectable women will not allow their daughters to go into it, and most women prefer to work in the mills if possible. The rugs are made from tailors' clippings, which are twisted round coarse twine, and woven on a hand loom. They are neither artistic nor very cleanly, being veritable receptacles for dust and dirt, but no rug as warm, or that will last so long, can be made at the price, and, consequently, there is still a large demand for them. Miss Slocock found in two or three cases the manufacturers were starting the works in other towns, transplanting one or two of their weavers to teach the women the trade, and when she visited Huddersfield later she was told that this experiment was proving satisfactory. The workers in this trade in Huddersfield had matters entirely in their own hands; they were all piece workers, and came and went as they chose. The system of fines for being late, and of selling the damaged work to the weavers, appeared to have been abolished, owing to the difficulty of obtaining workers, but there was a lack of discipline and order, and, except in the case of one or two workplaces, it was entirely in the hands of very rough, low-class women.

Cardiff.—The opening of the new dock at Cardiff calls attention to the really wonderful progress of that port during the last half century. In 1851 Cardiff was a town of 18,351 inhabitants, with a dock water area of 20 acres, and an aggregate import and export trade of less than a million tons. To-day it numbers 200,000 inhabitants, its dock accommodation covers 300 acres, with a trade of 25,000,000 tons, and it has become the greatest coal exporting centre in the world. It owes everything to the development of the South Wales coalfields. It has no great industries. A number of industries have indeed been established, and the port has become a ship-repairing and flour-milling centre, but it is not a great manufacturing or industrial centre like Newcastle or Glasgow. It is in its commerce and its shipping that Cardiff excels, merchantising as it does 70 per cent. of the coal product in the South Wales coalfields. It was between 1870 and 1890 that Cardiff developed most rapidly, and this increase was due to many causes, among them the increase in the size of steamships; the gradual displacement of sailing vessels by steam tramp vessels; the construction of the Suez Canal; the discovery of the superiority of Welsh steam coal over all other known coals for bunkering purposes; and the extension of the great railway systems of Great Britain and the continent. The output of South Wales coal rose from 13½ million tons in 1870 to 31 million tons in 1892, and the trade of the port of Cardiff grew from four million tons to some 14½ million tons. During these twenty years South Wales held practically a monopoly of the coal trade for railway, naval, and bunkering purposes in South Africa, India, and the Far East, and although since then the monopoly has ceased, the output of coal has grown continuously until in 1906 it amounted to nearly 47,000,000 tons, or 51 per cent. above that of 1892, whilst the trade of the port of Cardiff rose from 14,500,000 tons to 25,500,000 tons, an increase of 75 per cent. Nor has the growth of Cardiff as a shipping and ship-owning port been less remarkable. Fifty years ago Cardiff owned only a single steamer, a small coaster of about 600 tons dead weight. In 1906 she owned 250 steamships ranging in dead weight up to 10,000 tons, and representing an aggregate coal carrying capacity of over 1,250,000 tons. In 1870 the number of vessels cleared from the Bute Docks was 6,892, with a total net register of 1,618,733 tons. In 1906 the total number of vessels which cleared from the docks was 9,483, with a net register of 4,855,012 tons. The total tonnage cleared from the port of Cardiff in 1906 amounted to 9,961,502 tons as against 10,846,625 tons from Liverpool and 16,527,768 tons from London. If foreign cargo clearances alone are taken into account, Cardiff stands first with a tonnage of 8,089,773 tons, as against 7,291,039 from London, and 6,657,002 from Liverpool.

Harvest Prospects.—Although it is too soon to express any opinion upon yields, men of experience can say whether crops are healthy, with average growth and development for the time of year, and in accordance with its practice for many years past *The Times* has collected a number of reports from experts which show that while corn crops have suffered from excess of moisture and low temperature, grass is exceptionally abundant, and hay crops are heavy. On the whole the correspondents of *The Times* report favourably on the condition of most crops, but they are anxious as to the future. Complaints as to the backward, cold, and wet character of the season run through all the reports, but notwithstanding these adverse influences the figures show that the corn crops reached the end of June without serious injury. The writer of the digest, speaking from personal observation of the southern, eastern, and midland counties, says that on cold, stiff, lands the corn crops had evidently been seriously injured, and appeared yellow in colour, and very backward, but upon the warmer and lighter soils these crops looked well, although late, and oats were particularly vigorous and brown in the flag. Beans also were for the most part luxuriant. The wheat crop is likely to be less this year than last in England, and the decrease in Wales and in Scotland promises to be more serious than in England. Barley, too, is less promising than last year at this time, though more so

than in the corresponding period of 1905, and with favourable weather in the coming weeks the return is likely to be fairly good. Oats and beans look good, but the season has been less favourable for peas. It is too early to pronounce a definite opinion as to the potato crop, but its progress has been retarded by cold and wet weather. Estimates as to roots can only be taken as preliminary, and as indicating the present position of a class of crops which makes its principal growth after midsummer. In the Eastern, North Eastern, South Eastern, and East Midlands prospects are equal with those of last year, and superior to those of 1905, but the position is less promising in the West Midlands, the North-West, and the North. It is rather surprising, having regard to the damp, cold weather, to find the reports as to hops so favourable. Kent gives an average prospect of 84 per cent. against 60·5 last year; Sussex shows an average of 83 per cent. against 64·5 last year; Hampshire 90 per cent. against 54 per cent. last year, and Worcestershire 77 per cent. against 54 per cent. in 19.6. The area under cultivation this year shows urther shrinkage.

Coal.—Usually, almost invariably, the demand for coal, more especially house coal, reaches its lowest ebb in the summer, but this year instead of prices being reduced they are actually being increased. A few days ago, that is to say in the early days of July, and on the London market, north country house coal was advanced 1s. per ton, following a previous advance of 6d., and a similar experience is reported from other parts of the country. In the Lothians for the first time, as it is said, in the history of the local house coal trade, there was on July 1 an increase of 1s. per ton in splint coal. If this is the state of things in midsummer, what is likely to be the condition of the market when summer ends. The unusually cold season has no doubt had an appreciable effect on the market, but it is the great and growing export demand that is mostly accountable for rise in prices. It is stated that the Westphalian Syndicate has already sold the whole of its production up to the end of 1908, and in consequence of the difficult position in which it finds itself owing to the great home demand, it has been compelled to abandon one foreign market after another, a fact which has a very direct bearing upon our export trade. Add the general improvement in the trade of the United Kingdom, and the increase in the wages of the miners, and we have the explanation of the present almost unprecedented high rates for coal. Any way the coal-owners, relieved of the export duty on coal, which in five years yielded the Treasury £11,000,000, and which, if this explanation is to be accepted, was paid by them, must be specially prosperous.

The Growth of Insurance.—In opening the new offices of the United Kingdom Temperance and General Provident Institution, the Chancellor of the Exchequer directed attention to the growth of the office during the fifty years of its existence. "I find," he said, "that fifty years ago the total annual income of your institute was only £40,000, while last year it amounted to nearly £900,000. At the earlier date the accumulated funds were £115,000; they are now over £8,500,000, and the amount insured has risen from £1,250,000 to £19,000,000. But these figures, remarkable as they are, are to some extent typical figures. At the present time the life insurances actually in force number, in what is called the ordinary offices, over 2,397,000, and in the industrial offices 25,000,000, a total of nearly 28,000,000. In its annual insurance tables just published the *Statist* shows that "in the short space of 20 years the annual sums devoted to life insurance have grown from £16,000,000 to nearly £37,000,000, an expansion of £20,000,000 a year, or 125 per cent.; while the growth during the last ten years has been nearly £12,000,000, or 46 per cent." Seeing that the population of the country has during the last twenty years increased at the rate of only about 1 per cent. per annum, the magnitude of an expansion of 125 per cent. in the sums applied to life assurance will be apparent. In 1887 the sum devoted to life assurance was slightly over 9s. per head of population. According to the latest returns it is now over 17s. per head. The following figures show the sums now paid for life and old age assurance as compared with the figures of 20 years ago:—

	Annual Premium Income. £	Per head of Population.
1887	16,396,960	·459
1907	36,952,296	·853
Increase 20 years +	20,555,336	+ ·396
Do. per cent. .. +	125 %	+ ·86 %

The interest on the funds now accumulated by the life offices is close upon £12,000,000, and the total income of the life offices from premiums and interest is nearly £49,000,000. In 1895 the accumulated funds of the life offices amounted to £213,000,000, and in 1905 they were £327,000,000, a growth in ten years of £114,000,000. Including the accumulated funds of fire, accident, and marine offices, the total assurance funds accumulated by insurance offices of all kinds grew from about £246,000,000 in 1895 to £376,000,000 at the end of 1905, an increase in ten years of £130,000,000, or 53 per cent.

OBITUARY.

SIR WILLIAM PERKIN, F.R.S.—By the death on Sunday, 14th inst., of Sir William Henry Perkin, LL.D., Ph.D., D.Sc., founder of the Coal Tar Industry, the Society of Arts has lost a distinguished member. He was elected a member in 1868, a member of the Council from 1877 to 1879, and a Vice-President from 1880-1882. In 1890 he was

awarded the Albert Medal "for his discovery of the method of obtaining colouring matter from coal tar, a discovery which led to the establishment of a new and important industry, and to the utilisation of large quantities of previously worthless material." It was only last year that the fiftieth anniversary of his discovery of the dye stuff "mauve" was publicly celebrated and a knighthood was conferred upon the discoverer. An account of the proceedings of this important celebration will be found in the *Journal* (vol. 54, p. 901).

Sir W. Perkin was born on 12th March, 1838. He received his early education at the City of London school, but left school in his 15th year to enter the Royal College of Chemistry, then under the superintendence of Professor Hofmann. Here he became Hofmann's private assistant in the research laboratory. In 1856, in the course of attempts to prepare quinine artificially, he was led to oxidise aniline, and obtained as a product the colouring matter, which afterwards became known as aniline purple or mauve. He determined to undertake the manufacture of the dye (which was patented in August, 1856), and in June, 1857, aided by his father and brother, Perkin began building works at Greenford Green, near Harrow, where the manufacture was carried on successfully during many years.

In 1859 the Société Industrielle of Mulhouse awarded Mr. Perkin a silver medal and afterwards a gold medal for his discoveries.

In 1868, when Graebe and Liebermann announced their discovery of a laboratory method of preparing madder-red or alizarin, Perkin devoted himself to searching for new processes by which the discovery could be made practically valuable. He succeeded in his endeavours, and alizarin was first manufactured commercially at Greenford Green in 1869. Besides these two great works, Sir William Perkin made many other discoveries, and contributed a large number of original papers to the Journal of the Chemical Society. He was elected a Fellow of the Royal Society in 1866, and in 1879 he received the Society's Royal Medal for his researches in organic chemistry, and ten years later the Davy Medal. Sir William Perkin delivered in December, 1868, three lectures before the Society of Arts on the Aniline, or Coal Tar Colours, and in May, 1879, two lectures before the Chemical Section on "The History of Alizarin and Allied Colouring Matters, and their production from Coal Tar."

GENERAL NOTES.

PETROLEUM IN ROUMANIA.—The petroleum industry is becoming a very important one in Roumania. The total production in 1906 was 887,091 tons, an increase of about 45 per cent. over that of 1905, and Roumania now produces more petroleum than any other country save he United States, Russia, and the Dutch Indies. Roumania is very favourably situated geographically, and the new sources of supply which are constantly being discovered seem to give justification for the belief that she may gradually gain a dominant position in this article, in which she is already unrivalled from the point of view of quality. Reporting on the trade of Roumania for 1906 Mr. Consul Wardrop (Cd. 3283) says that experiments made by the Service Maritime Roumania have shown that on every trip made by their steamers there is a saving of more than £40 due to the use of this fuel, besides the additional advantages of cleanliness, saving of space, and fewer hands. The Roumanian naval and mercantile fleet is the only one which exclusively uses petroleum fuel. It checks the destruction of the forests, saves large expenditure on foreign coal, guarantees fuel in case of war, lessens the dependence of the country on grain export alone for its prosperity, gives wealth to the people, taxes to the State, and traffic to the railways.

SANTO DOMINGO.—Mr. Vice-Consul Rowley's report on the trade and commerce of Santo Domingo, better known by its old carib name of Haiti (highland), is melancholy reading. The black Republic makes little or no progress. In 1903 it was bankrupt, and found itself compelled to suspend payment of the interest on its foreign loans and debts; the foreign debt amounting to about £6,185,000, and the internal debt to about £2,061,855, and although the convention with the United States, drawn up in February last, will improve the financial position, the trade and commerce of the Republic show few signs of expansion. Santo Domingo is, practically speaking, destitute of even the ordinary waggon road, the horse or cattle tracks being the only means of communication between the towns, villages, and sea ports. The majority of the people, says Mr. Vice-Consul Rowley (Cd. 3283), are most indolent, and cultivate barely sufficient ground to raise the necessary cereals for their own use, the markets in the various towns are meagrely supplied with even the most necessary vegetables, and as nothing worth mentioning is manufactured, or made locally, everything has to be imported. The customs duties on all articles are exceedingly high, and many pay as much as 300 per cent. There are no sanitary or water systems in the capital, the former consisting of the ordinary cesspool, and the latter of the usual open well fed from the water collected off the roofs of the houses. Although the rainfall is enormous the people suffer greatly from want of water during a drought of a few days, and in March last the Vice-Consul says the people at Sanchez were buying water at the rate of ninepence a demijohn. The people are too lazy to build cisterns, and the barrels they use being open to the air offer an inviting breeding ground for innumerable mosquitoes, as well as dust, dirt, and disease germs.

Journal of the Society of Arts.

FRIDAY, JULY 26, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

PRACTICAL EXAMINATIONS IN MUSIC.

The practical examinations in Music were not concluded this year until the 10th July, too late for the results to be included in the Report of the Council. They lasted for 12 days

The examination was conducted by Dr. Ernest Walker, M.A., and Mr. Burnham Horner.

The system of examination was the same as that for recent years. For instrumental music certain standards are given, and candidates are asked to select for themselves which of these standards they choose to be examined in. The standards range from easy to very difficult music. For each standard a list of music is given for study, and from this list candidates select the pieces they will sing or play. Candidates are expected to play or sing the pieces which they have prepared, to play or sing a piece, or portion of a piece, at sight, and to play certain scales.

In all, 466 candidates entered, and of these 457 were examined, a decrease of 10 as compared with last year. There were 371 passes and 86 failures.

The following were the subjects taken up :— Piano, singing, violin, violoncello, viola, and bassoon. 371 entered for the piano, 292 of whom passed ; 67 entered for the violin, of whom 61 passed ; 5 entered for the violoncello, of whom 4 passed ; 12 entered for singing, all of whom passed ; one entered and passed for the viola, and one for the bassoon. One medal was awarded.

The examiners report that—

" Some of the candidates were, perhaps, not wisely advised in entering for a standard too high for their present attainments. A few pianists chose items from the lists issued in 1906, and others were not fully equipped for the reading test at first sight. This latter qualification needs to be better observed by vocalists, as well as by those who enter for other subjects. Tone and touch have somewhat improved, but there are many cases in which very little attention is given to phrasing."

STOCK PRIZE.

FOR THE DECORATION OF PART OF THE INTERIOR OF A BUILDING.

The Council of the Society of Arts are prepared to offer, under the terms of the Stock Trust, a Gold Medal, or a Prize of £20, for

The Prize is offered for the best original designs for an Architectural Decoration, to be carried out in painting, stucco, carving, mosaic, or any other process.

This Architectural Decoration is to be for the side of a room or a hall, a ceiling, the apse or side of the chancel of a church, or any suitable part of the interior of a building.

The designs must be on imperial sheets. Each set must consist at least of a coloured drawing to scale of the whole design of decoration, and two coloured drawings of details on separate imperial sheets. Mere patterns or sketches of details, without the mouldings or borders necessary to make up a complete decorative scheme, will not be taken into consideration. The designs must have been made between 1st April, 1907, and 31st March, 1908.

The recipient of a prize awarded under this trust in 1893 or 1897 cannot compete again.

The designs are to be submitted, with other school work, in the usual manner, to the Board of Education, South Kensington, in April, 1908. Each of the imperial sheets, forming a set of competing designs, must be marked, " In competition for the Stock Prize," in addition to being labelled or staged according to the Regulations of the Board of Education.

THE SAND-COUNTER OF ARCHIMEDES: A FAMOUS FRAGMENT OF SCIENTIFIC HISTORY.

By T. E. Young, B.A., F.R.A.S.
(Late President of the Institute of Actuaries).

Separated by an interval of 1,850 years, the two most memorable names in the history of mathematical science are those of Newton and Archimedes. Adopting a form of illustration which Professor Tyndall applied in comparing Newton with Dr. Thomas Young (of "Undulatory" and "Hieroglyphic" fame), and employing the scale of native mathematical force, it may reasonably be stated that, supposing Archimedes and Newton to stand erect, each in his own age, a straight line drawn from the former to the latter, and tangent to the heads of both, would exhibit a very gently ascending gradient only, as the measure of their comparative intellectual stature. Alike in swiftness and sureness of intuition, in massiveness of mental concentration, and in virtually unerring grasp of mathematical relations, they reveal the rare heights of geometrical power, which the human brain in its finest moulding is competent to reach.

In science, where every region displays an impressive advance, the difficulty is extreme of equitably assessing the mental value of a past worker and the novelty and importance of his productions in the scale of intellectual accomplishment: the imposing mass of existing knowledge tends to dwarf his contribution to the store; and it demands a strain of detachment from the present and the exercise of the dramatic power of translation into other times and ranges of thought before a valid judgment can be framed. It becomes imperative, as a rule of measurement, to attempt the construction of the ratio of his achievements to the extent of knowledge and capacity in his era. On this ground it is proposed to preface an exposition of the scheme of numeration which Archimedes devised, and the concrete problem upon which he tested its capability, with a brief outline of the condition of arithmetic at his date—his treatise having been composed somewhat earlier than the year 215 B.C. As Dr. George Peacock—the most learned of the historians of arithmetic—has pointed out, it is hardly possible to describe that condition with punctual certainty, since changes of notation occurred whose approximate dates of introduction cannot be ascertained; but, at all events, the following sketch exhibits the utmost extent to which the Greek arithmetical system could have, or had, attained. The symbolic expression, by the letters of the alphabet, of the 9 digits, the 9 tens, and the 9 hundreds, required the employment of 27 letters; the Greek alphabet containing 24, two obsolete letters were revived for 6 and 90 respectively, and as the representation of 900 a symbol was borrowed from the Phoenician alphabet. Thus, the first 9 letters symbolised 1 to 9 successively, the next 9 expressed the tens from 10 to 90, and the remaining 9 represented the hundreds from 100 to 900. The indication of thousands was effected by suffixing an iota (ι) to the letters which marked the 9 digits; thus δ being expressive of 4, δ_ι denoted 4,000; and hence they obtained an additional set of numbers ranging from 1,000 (by increments of 1,000) to 9,000. Their arithmetical notation consequently was restricted, so far as the preceding symbols were serviceable, to the number 9999. In their language, however, they possessed a term—μυριάς (myriad)—for the succeeding unit of 10,000 without a corresponding literal symbol; and, in practice, they secured the advantage of this factor by subscribing the letter M or postscribing the letters Mυ to the alphabetic symbols for any of the numbers included in the scheme. Thus θ, which expresses 9, was converted into 90,000 (or 10 thousand-fold) by writing it $\overset{\theta}{\mathrm{M}}$ or θ Mυ. Hence they reached a final limit of 8 places of figures or 9999 9999. Intermediate numbers, such as 11, were indicated as the sum of 1 and 10; as ι represented 10, and α, 1, their sum or 11 was symbolised by $\iota\alpha$. This practice does not imply a recognition of our modern principle of local value, for each of the alphabetic characters always retained its definite numerical value, and consequently the order of $\iota\alpha$ or $\alpha\iota$ did not affect the result as in modern notation. In actual arithmetical operations, however, the Greek was virtually confined to the myriad, and any vast number was regarded as beyond the range of numeration, or was deemed to be coincident with infinity. In their current modes of calculation the case of multiplication may be cited. The operation was conducted from left to right; each product was recorded separately without incorporation with those which preceded or followed, and in any order or without order; and the several products were then collected and added into a total sum. Where the results of the multiplication of numbers were not contained in the simple

multiplication-table (committed to memory) they were, as a rule, generally obtained, not by the Abacus, but by the cumbrous process of repeated additions. A remarkable novelty in multiplication will appear in the explanation of the method of Archimedes.

The title of the work of Archimedes is Ψαμμίτης (= sand), but it is usually described as the Ārēnārĭus, or sand-reckoner (ărēna = sand), or the De Numero Arenae. He had published a prior work upon the principles of Numeration (entitled 'Αρχαί), which has been lost; the scheme there proposed is, happily, repeated in its essential features in the present book,—Archimedes stating that this course would be convenient to those who had not had the opportunity of perusing his previous monograph. The terms expressive of the values of numbers up to a myriad having been delivered from tradition, Archimedes remarks that a continuation of the process will produce the myriad of myriads (or 100,000,000); he then proposes to extend this method in a form adapted to avoid the confusion incidental to vast numbers so that the highest assignable numbers might possess the facility of expression and use which attached to the simpler numbers. For readiness of understanding, I shall employ ciphers, instead of letters, throughout, although the zero (of Indian origin) was not introduced until about 600 or 700 years subsequently; it is the comprehensive *method* of Archimedes that concerns us.

(α). A series of consecutive numbers is formed, starting from 1 as its unit; this unit is multiplied successively by 10, 100, up to 10,000,000 (or 1000 myriads); 8 terms are thus obtained, and the collection is designated the 1st degree of myriads; each term possesses its name: the 1st of the degree is the unit, the 2nd is the tens, the 3rd the hundreds, the 4th the thousands, the 5th the myriads, the 6th, tens of myriads and so on. This mode of description applies to every degree of myriads; and each degree is generally termed an octade as consisting of 8 terms.

(β). The 8th or final term of the 1st degree is multiplied by 10, and the product constitutes the unit (or, as it is sometimes named, the monad) of the 2nd degree of myriads, or 100,000,000. A 2nd octade is thus started with this unit. Multiplying such unit, as before, by 10, we obtain the 2nd term of the 2nd degree, or the tens of that degree: the multiplication of the unit by 100 (making 10,000,000,000) produces the 3rd term or the hundreds of the 2nd degree; and the final multiplication of the unit by 10,000,000, *i.e.*, by thousands of myriads (as was done for the corresponding term in the 1st degree), furnishes the 8th term of the 2nd degree or 1 followed by 15 cyphers. Thus 8 additional terms are constructed, and in the last term of this degree we have reached the 16th term in the consecutive series. The 8 terms here formed compose the 2nd degree of myriads or the 2nd octade. (It is proposed hereafter, where the numbers largely increase and the plan is feasible, to adopt, for brevity, the convention invented for the expression of ciphers by the mathematician, Benjamin Gompertz, who employed a circle with the number of ciphers inscribed—thus 1,000,000 is symbolised by 1 (6); on my mentioning this artifice to the late Mr. Gladstone, with which he was greatly pleased, he communicated to me a somewhat similar device of his own for aiding his remembrance of extensive round figures in his Budget speeches).

(γ) The 3rd degree of myriads is constructed in the same manner. The 1st term or unit consists of 10 times the 8th term of the 2nd degree, and is 1 (16): multiplying this unit successively, as before, the final or 8th term of this particular degree is produced, or 1 (23),—thus bringing us to the 24th consecutive term of the entire series, and the conclusion of the 3rd octade.

The last term of any degree, it will be noticed, is formed by the multiplication of the unit of that degree by 1,000 myriads.

(δ) The process is continued, degree by degree, up to the degree which Archimedes designates the myriomyresimal degree of myriads, *i.e.*, the (myriad of myriad)th degree or the (100,000,000)th degree. It is needless to describe the intermediate steps—the 4th, 5th, and sequent degrees—as the uniform mode of formation is sufficiently clear, or to calculate the values of the several 8 terms which constitute this final or myriomyresimal degree. We can at once express any term required, and any term of any degree, by following the method of construction. Thus, we may directly ascertain the unit and the 8th term of this ultimate degree. The unit of the 1st degree consists of one figure; the unit of the 2nd of 9; that of the 3rd of 17, and so on: hence the number of figures constituting the units compose an arithmetical progression whose common difference is 8. Employing, then, the usual formula for the last term of such a progression, we obtain for the unit of

the myriomyresimal degree (the number of degrees up to, and including, this stage being a myriad of myriads) $1 + (100,000,000 - 1) \times 8$ or 799999993; or the unit or monad of the myriomyresimal degree is a number which can only be expressed by 799999993 figures, *i.e.*, 1 followed by 799999992 ciphers. For the 8th, or last, term of this degree, we observe throughout that the number of figures in the final term of any degree is obtained by multiplying the number of the degree by 8; hence, the last term of the myriomyresimal degree is 100,000,000 (the number of the degree) multiplied by 8, or consists of unity with 799999999 ciphers annexed. It is also obvious that, in any degree, the number of figures comprised in its last term is found by adding seven figures to its unit or by adding eight figures to the number of figures in the 8th term of the preceding degree.

(ϵ). It may be added that the unit of any degree is otherwise termed "myriad of myriads" of the preceding degree: *e.g.*, the unit of the 2nd degree is 100,000,000, and this is the unit of the 1st degree (or 1) multiplied by a myriad of myriads (or 100,000,000).

(ζ). The 5th term of any degree, it may be repeated, is also named "myriads" of that degree, since it results from the multiplication of the unit of that degree by a myriad. And the final or 8th term of any degree is designated "thousands of myriads" of that degree for a similar reason. These and other features are noticeable on inspection.

(η). Archimedes then remarks that the stage of numeration attained in the construction of the myriomyresimal degree affords numbers sufficiently ample for the solution of the problem of sand-counting; but, to display the power of the method, he advances to a further extension.

(θ). Designating the whole of the numbers comprised within the myriomyresimal degree as the 1st period, he proceeds by successive 10-fold multiplication in the same mode to higher classes. Thus, multiplying the number in the final term of the myriomyresimal degree by 10, he obtains the unit of the 1st degree of the second period, consisting again of 8 terms. Pursuing this continuous multiplication, and retaining the plan of octades, he forms the 8 terms of the 2nd degree of the 2nd period; and, finally the myriomyresimal degree of that period. The 8th term in that myriomyresimal degree being multiplied by 10 furnishes the unit of the 1st degree of the 3rd period, and thus the myriomyresimal degree of that period is finally attained. Similarly for the myriomyresimal degree of the 4th and subsequent periods. And, ultimately, where his process terminates, he reaches the myriomyresimal degree of the myriomyresimal period, the unit of which is a number composed of 79999 9999 9999 9993 figures, or 1 followed by that number, less 1, of cyphers; while the 8th, or concluding, term of this vast period consists of eighty thousand million of millions of figures or unity with a number of ciphers annexed equal to the number just expressed less 1. The reader should bear in mind that these numbers—and the remark applies to some other numerical expressions—are not numbers proper but the number of the places of figures which constitute the stated numbers. The preceding number being the final term in the myriomyresimal series, which starts with the 8th term of the 1st period, its value can be directly computed by the usual formula applicable to an arithmetical progression; but a little consideration of the structure of the scheme will show that it is obtainable at once by multiplying the last term of the 1st period by a myriad of myriads.

Although Archimedes concludes his system at this stage, it is obvious that the process is capable of indefinite expansion. For the whole of the numbers (following his own device) included in the scheme as terminated by him may be symmetrically regarded as a fresh point of departure, and be called (say) the 1st era, with additional vast stages of similar construction.

The analogy of this principle of formation with our existing methods should be noted. The 1st degree of myriads ends with 1,000 myriads; our 1st degree of thousands terminates with 1,000 thousands, or a million; the 2nd degree of myriads is completed by 1 15, or 1,000 myriads of myriads of myriads; our 2nd degree of thousands ends with a billion, or 1,000 thousands of thousands of thousands; the 3rd degree of myriads concludes with a number which is 1,000 of myriads of myriads of myriads of myriads of myriads; while our trillion, or 3rd degree of thousands, is composed of 1,000 thousands of thousands of thousands of thousands of thousands, and so on: precisely, therefore, corresponding to the scheme of Archimedes.

A very striking plan is deduced (anticipating, though unconsciously, the principle involved in the construction of logarithms) for determining the position in the series of the product of any two stated terms. If any two terms (we might

more properly say, numbers) be multiplied together, the place in the series of their product will be furnished by the sum of the distances of the two terms from unity (*i.e.*, from the 1st term of the entire series) diminished by 1. Thus, if from the series of numbers on a former page the two terms selected be the 3rd from unity (*i.e.*, the third term of the 1st degree) and the 12th from unity (*i.e*, the 4th of the 2nd degree) the product of the numbers appertaining to these terms (namely, 1 (2) and 1 (11)) is 1 (13). The respective distances from unity of the two terms (counting in, as Archimedes does, the 1st term or unity) are 3 and 12; consequently, the place in the series of the product is furnished by $3 + 12 - 1 = 14$. And a reference to the figures, already presented, shows that the number 1 (13), *i.e.*, 1 with 13 ciphers annexed, does occupy the 14th place. It is obvious that unity must be deducted from the sum of the distances, or—since the distances of the two terms necessarily overlap—a unit of distance (or a term) would be reckoned in twice. This is evident if we compute the distance from unity of the later term as the sum of the distances of the earlier term from unity, and of the later term from the (inclusive) place of the earlier one.

He also points out that the different denominations by which numbers are distinguished from each other exactly correspond, by the method of construction, to the several 8th places from unity. His exposition is not very clear, and the following explanation may be substituted. Let any term be stated, or let the number of figures appertaining to any term be given; the number of figures, then, in any number being identical with the consecutive number of its term, we may deal with either the term itself or the number of figures in the number. Divide the term (or number of figures) by 8, the characteristic element; if the quotient contain an integer only, the degree to which the term or number belongs is that particular degree indicated by the integer, and the 8th term of that degree is designated. If the quotient contain a remainder besides the integer, the integer specifies the number of the degree from which we are to reckon onwards to the extent shown by the remainder, when we shall reach the relevant degree and its term. Take the 16th term, or the number composed of 16 figures; the quotient is 2, and as there is no remainder the place of the term or number in question is the 8th term of the 2nd degree. Take the 13th term, or a number of 13 figures; the quotient of 1 with a remainder of 5 points to 5 terms beyond the end of the 1st degree (shown by the integer), or the 5th term of the 2nd degree. The application of the scheme to the concrete problem is now to be described.

1. A sphere of the size of a poppy-seed cannot contain, it is assumed, more than a myriad (10,000) particles of sand, and its diameter is not less than one-fortieth (or ·025) of an inch. Archimedes found, by trial, that the actual diameter was nearer ·04 of an inch, but he adopts an exaggerated fraction as a severer test of his system. Archimedes was aware that the contents of spheres are to each other as the cubes of their diameters; hence the proportion—the sphere of a poppy-seed: a sphere of 1 inch diameter : : the cube of ·025 : the cube of 1,—furnishes the volume of a sphere of 1 inch in diameter, which is the volume of the smaller sphere multiplied by 64,000. But the volume of the smaller sphere is measured, by supposition, by its containing not more than 10,000 particles; hence the larger sphere will contain a number of particles less than $10{,}000 \times 64{,}000$ or 640 millions: this number consists of $600{,}000{,}000 + 40{,}000{,}000$, or (referring to the scale already partially presented) 6 units of the 2nd degree and 4,000 myriads of the 1st degree. This is clearly less than 10 units of the second degree, whose unit multiplied by 10 gives 1,000 millions. A similar process furnishes the superior limit of the number of particles in successively larger spheres until the sphere of the earth is reached.

2. The earth's circumference was estimated by the scientific contemporaries of Archimedes to be nearly 300,000 stadia. A fair average value of the στάδιον (the measures of the authorities on classical antiquities differing) may be accepted as 600 English feet, so that this estimate was about 10,000 miles in excess of the true value. For the same purpose of demonstrating the practical extent of his numerical system, Archimedes accepts a circumference of 10 times the current value or about 3 million stadia. He had himself, by a geometrical process, ascertained that the ratio of the circumference of a circle to its diameter (or π) was greater than 3 and 1/7 and less than 3 and 10/71—a remarkably close approximation—and hence was able to calculate the earth's diameter from this exaggerated circumference, placing it at less than one million stadia (about 14 times its computed real value). Summarising the pro-

cess of Archimedes, we can determine the volume of the earth from that of the sphere of one inch by the ratio of the cubes of the diameters. Hence, the volumes being measured by the numbers of included particles of sand, the appropriate proportional sum expresses that the number of particles capable of being contained in a sphere of the earth's size and completely filling it will be the number of particles contained in the sphere of one inch (the inch being about ·00014 of a stadion) multiplied by the cube of the earth's assumed diameter. Working this out in detail, I find that the required number of particles can only be expressed by a number comprising 39 figures. Archimedes simply states that the number is less than 1,000 myriads of the 5th degree. The two results coincide: thus, the 8th term of the 4th degree has $4 \times 8 = 32$ figures; the next term, or the unit of the 5th degree, has 33, the 2nd term has 34 ..... and the 5th term (or myriads) of that degree has 37 figures, and the multiplication of that number by the 1,000 gives 40 figures, or a number in excess of ths calculated value. Thus, the number of particles possible of inclusion within the entire volume of the earth is measured by a number which appears in a very early stage of the series of Archimedes.

4. What number of particles, then, could be included within the sphere of the world or κόσμος? Scientific opinion (including that of Archimedes) regarded the earth as the centre of the world, and the radius of the world's sphere or of the cosmical universe was measured by the distance between the sun and the earth. A fact is here worthy of record as indicating the probable fate of many a memorable deduction of genius. The astronomer Aristarchus (who was contemporary with Archimedes) entertained the view that the sun was immoveable as the centre of the universe, round which the earth annually revolved. The sphere of this universe was hence conceived by Aristarchus to be immeasureably more vast than the limited expanse which the current astronomical doctrine defined. Thus, Aristarchus anticipated the conception of the true cosmical system by 1800 years, and yet, had not this incidental allusion been preserved in the treatise of Archimedes, that remarkable reach of scientific vision which renders the name of Aristarchus illustrious would (so far as authentic evidence is concerned) have remained unknown. Archimedes rejected the teaching of Aristarchus upon the spaciousness of the universe, but included it in his calculations simply with the object of displaying the ample scope of his numerical scheme. The mathematical form in which, it appears, Aristarchus had embodied his conception was repugnant to the severe geometrical taste of Archimedes, and he accordingly interprets the Aristarchian doctrine to mean that the ratio of the earth to the sphere of the κόσμος (as customarily understood) was the same as the ratio of the latter to the enlarged sphere of Aristarchus. But first he considers the number of sand-particles which the accepted sphere of the world was competent to contain. This number he ascertains to be less than 1,000 of the 7th degree of myriads. We can confirm this by the adoption of the four proportionals expressed by the volume of the earth, the volume of the sphere of the world, and the cubes of the diameters of these spheres. By an ingenious course of geometrical reasoning (founded upon the data then available) Archimedes deduced that the diameter of the sphere of the world was less than 10,000 times the earth's diameter. Hence we obtain our proportion: as the number of particles which the earth can contain is to the number capable of being comprised within the sphere of the world, so is the cube of the earth's diameter to the cube of the diameter of the world's sphere. The calculation shows that the multitude of particles which the world's sphere could include requires for its expression a number less than a number consisting of 52 figures. This agrees with the preceding assertion of Archimedes. For the 8th term of the 6th degree of myriads contains, as can be readily computed, 48 figures; and proceeding to the thousands of the 7th degree (or 4 figures more) we obtain 52.

5. Archimedes then proceeds with the same enquiry relating to the extended sphere of the universe of Aristarchus. He first determines the diameter of this sphere to be less than a myriad times the diameter of the world's sphere on the current hypothesis: it is, however, sufficient to adopt the following proportion: the volumes of spheres being related to each other in the triplicate ratio of their diameters, and these volumes being measured by the number of sands which the spheres are capable of comprehending, we obtain the proportionals,—the number of sands contained in the earth is to the number comprised within the sphere of the world as the latter number is to the number we are seeking for the Aristarchian κόσμος. This works out, by my calcu-

lations, at a number less than a number comprising 64 figures, or 1 with 63 ciphers attached. Archimedes summarily assesses the number at less than 1,000 myriads of the 8th degree. Now, the last term of the 7th degree contains $7 \times 8 = 56$ figures; and counting onwards through the unit, tens, ... to the myriads of the 8th degree we arrive at a number consisting of 61 figures; multiplying this by the 1,000 (to obtain the 1,000 myriads) we reach a number constituted by 64 figures, which shows the coincidence of the two calculated results. That is to say, the multitude of particles of sand which could be included within the compass of the Aristarchian universe may be expressed by a number less than 10 raised to the 63rd power. A number, therefore, which the scientific and ordinary mind of that age regarded as impossible of numerical expression, is comprised within the 8th degree only of the vast system of Archimedes. As the number of any term in this continuous series is identical with the number of figures in the number attached to that term, the number in question constitutes only the 64th term in the series from unity.

Reference may here be made to a calculation contained in the "Principles of Science" of the late Professor Jevons. He takes the number 2; 2 raised to the 1st power (= 2) he terms the 1st order; 2 squared or 4 is the 2nd order; 2 to the 4th power or 16 constitutes the 3rd order; 2 raised to the 16th power forms the 4th order. Now, 2 to the power of 16 is 65536, and we thus ascend at one step from a stage of 16 to one of 65536; but advance one further step to the 5th order, or 2 raised to the power of 65536, and the result can only be expressed by a number consisting of 19729 figures. Now the distance of the remotest telescopic stars from the earth is about 33,900 million million miles. Lord Kelvin has calculated that a cubic centimetre of a liquid or solid substance does not contain more than 3×10^{24} to 10^{26} molecules—the molecule of ordinary matter possessing a diameter from one ten-millionth to one one-hundred-millionth of a centimetre; hence this stupendous sphere of the stellar universe—a sphere measured by a radius of 33,900 billion miles —would not comprise, if completely filled with solid matter, more molecules in number than about 68×10^{90} or a number for whose expression 92 places of figures would be required —a number immensely inferior to the 5th order of the powers of 2. By independent calculation and using the formula for the volume of a sphere, I have exactly verified this result. We can readily ascertain that this number would form the 4th term of the 12th degree of Archimedes. (The diameter of the molecule, just mentioned—taking the mean value—is equivalent, when expressed in British measure, to 1/137,500,000 of an inch. Archimedes does not specify the diameter of his particle of sand, but it may be approximately calculated. If x be the volume of a particle, then $10000\,x$ is to be equated to the volume of a sphere of one-fortieth of an inch in diameter. From the value of x thence deduced, its diameter can be ascertained by the usual formula, and the diameter of a particle of sand in the problem of Archimedes is thus found to be 1/862 of an inch. It may also be mentioned that the radius of the Aristarchian sphere adopted by Archimedes comprises 6 billion miles compared with the preceding figure for the stellar universe.)

It forms an impressive coincidence—though, as Dr. Peacock has stated, justly, I think, a coincidence only—that the principles of this method and of the theory of logarithms are identical. It is worth while exhibiting this congruity in a brief form. I have prepared the following suggestive Table:—

Number of the term in the series.	The numbers of Archimedes.	Logarithms.
1	1	$10^0 = 1$
2	10	$10^1 = 10$
3	100	$10^2 = 100$
4	1,000	$10^3 = 1{,}000$
5	10,000	$10^4 = 10{,}000$
6	100,000	$10^5 = 100{,}000$

In the 3rd column, the index of the base of logarithms, 10, is termed the logarithm of the number on the right-hand side of the equation, so that $10^2 = 100$ expresses that 2 is the logarithm of 100 to the base of 10; and it will be observed that the logarithms increase in arithmetical progression while the corresponding numbers increase in geometrical progression. Hence we perceive:—

(1) That the numbers to which the base (raised to the several powers) is equated coincide with the numbers of Archimedes in the same terms; or, thus expressed: just as the logarithms proceed in arithmetical progression and the numbers of which they are the logarithms in geometrical progression, so, in the scheme of Archimedes, the terms advance in arithmetical progression and the numbers

attached to those terms in geometrical progression.

(2). If we desire to find the product of the numbers in (*e.g.*) the 2nd term and the 4th term, we add the logarithms in those terms, *i.e.*, the indices; thus, $1 + 3 = 4$, and 4 is the logarithm of the product or the 5th term, and the number corresponding to this logarithm is seen to be 10,000, which is the product of the number in the 2nd term (or 10) and the number in the 4th term (or 1,000). Similarly Archimedes adopts the course of finding the same product; the distances of the terms, 2 and 4, from the unit or 1st term are 2 and 4; their sum is 6; deducting 1 we obtain the place or term of their product, namely, the 5th, or 10^4, *i.e.*, $10 \times 1{,}000 = 10{,}000$, as before.

(3). It is needless to enlarge (in contrast with the cumbrous and intractable nature of the traditional Greek notation) upon the facility in computation and in the reference of numbers to their appropriate places in the series which was introduced by the methodisation of his scheme in sets of octades as a fundamental property of his numeration. By adopting this artifice it will be observed that the units or 1st terms of the several degrees are really the base of 10 raised to the successive powers of 8 in arithmetical progression; thus, the unit of the 2nd octade is 10^8, that of the 3rd, 10^{16}, and so on.

The coincidence is remarkable. But, in all probability, neither the extent nor the character of mathematical knowledge existing in the age of Archimedes, nor the nature of the question which he discussed, could suggest the definite establishment of the formal system of logarithms with their fundamental property that the sum of any two logarithms should be equal to the logarithm of the product of the numbers to which those logarithms corresponded. The immortal invention of Napier, accordingly, would appear to remain unchallengeable; and this is not the first occasion in the history of inventive thought on which a sagacious discoverer has verged closely upon the detection of an illuminating principle which has profoundly modified the entire condition of scientific work.

The mathematician, M. Chasles, in a paper contributed, in 1842, to the French Academy of Sciences, presented an excellent summary of the modes of admiration which scientific men had expressed, in modern times, of the ingenuity and value of this treatise; the arithmetician discovering in the method an analogy with the modern principle of the value of local position in numeration; the algebraist extracting from it the principle which lies at the foundation of the theory of logarithms; the geometrician extolling the geometrical processes which Archimedes devised and pursued in the course of his enquiry; and the astronomer dilating upon the admirable manner in which Archimedes had conducted the geometrical investigation for the determination of the distance of the sun. But one main object of M. Chasles' exposition is the proof that the treatise was not intended to simplify and expand the numeration of the Greeks; that the principles of numeration were only introduced incidentally, and that the essential purport of the book was the philosophical and mathematical one of destroying an immemorial error with respect to the impossibility of assigning by numbers a superior limit to the multitude of grains of sand which the earth could contain. A critical analysis of the tract clearly demonstrates, I consider, that this judgment of M. Chasles is erroneous, and that it is even constructively contradicted by the form of the book itself and by certain expressions which Archimedes employs. The principles of his system of numbers were expounded by him in a prior treatise, which is not now extant, and which (inferentially) was unaccompanied by any practical application. If Archimedes had designed to subvert, as his main purpose, an ancient error respecting the numeration of sands, the concrete illustration would surely have found its appropriate place in the first tract as an admirable example and commendation of the power of his method. This illustration very evidently did not appear in that work, for Archimedes, in quoting from the monograph, never refers to the sand question as having been there discussed; and, moreover, it would have been an irrational surplusage of authorship to issue two treatises upon one identical problem. At the commencement of the present book, Archimedes states that the magnitude of the number of sands in Syracuse, and in the rest of Sicily, was regarded as innumerable; much more so, then, would it be maintained that no system of numbers could be discovered to express the multitude of grains in the entire world. This evidently shows that an objection had been raised to the scheme of his former work on the practical ground of its general incapability of application to actual cases. He affirms that he can prove geometrically that the terms for numbers which he had formerly proposed were competent to afford a complete answer to the problem

and also to a much wider one submitted by himself. He then repeats an abstract of the numerical processes from the earlier book, and applies them to the refutation of the popular belief in the impossibility of numbers being invented for the solution of the concrete problem even in its limited shape. Hence, the primary object of the treatise was not the exposure of an ancient error, but the re-affirmation of the principles he had already enounced *by means* of their application to a specified case. The solution of a problem of this minor importance would not, as a mere problem, have been worthy of the devotion of the consummate geometrical power of a mathematician like Archimedes, but the problem was highly worthy of investigation as a mode of confirming and practically exhibiting the general applicability and range of the method which he had already submitted to the scientific world.

THE GOVERNMENT PATENT BILL.

The following letter was printed in *The Times* of 19th inst.: —

"SIR,—The Patents and Designs Bill (as amended by Standing Committee C) contains the following clause: —

"7. The following proviso shall be added to subsection (6) of section 1 of the Patents Act, 1902: —

"'Provided that the Comptroller, if satisfied that the invention claimed has been wholly claimed or described in any specification to which the investigation has extended, may, in lieu of requiring references to be made in the applicant's specification as aforesaid, refuse to grant a patent.'

"Under subsection (6) of section 1 of the Patents Act, 1902, which was the outcome of careful inquiry and report by a strong Departmental Committee, including Sir Edward Fry (chairman), Lord Alverstone, and Lord Justice Fletcher Moulton, the Comptroller already has, and exercises, power to require specific reference to be made in the applicant's specification (by way of notice to the public) to any prior specification which in the Comptroller's opinion anticipates the invention claimed by the applicant.

"It is therefore quite impossible for an applicant to deceive the public as to the novelty of his invention, or to conceal from the public any alleged anticipation. If the invention be really anticipated, the applicant's specification will itself at once condemn his patent, and the grant can do no harm.

"But whether or not the invention described and claimed by an applicant is wholly anticipated is essentially a matter of opinion. Experience shows that a man looking at a publication some years old, when he has an invention before him, reads that publication in a very different spirit from that in which he would read it if he had not known of the invention then before him; and it is not an uncommon thing for an examining official to interpret as an anticipation that which is no real anticipation. In the High Court of Justice it requires the most profound judicial heads, often, to distinguish what is anticipation and what is not.

"Indeed, it may be affirmed that, in all cases where patents have been sustained for doubtful subject-matter, they have been sustained on the ground of great benefit or advantage having been found to result from the use of the invention. At the time of applying for a patent, however, it is often impossible to have evidence of such utility, and neither the Comptroller nor (in case of appeal) the Court can be expected to look into the future of an invention which at first b'ush may seem to have been anticipated.

"Even in countries where the strictest examination obtains, coupled with power of refusal for supposed anticipation, many invalid patents are granted.

"A patent that leads to commercial introduction of an article not previously on the market conduces to industrial activity and employment of workpeople, and therefore is advantageous to the community, even should the patent subsequently prove to be invalid. Moreover, the Bill contains ample provision for revocation of invalid patents.

"But a single error in judgment, resulting in refusal of a patent on the ground of supposed anticipation, may inflict irreparable injury upon the applicant, prevent profitable outlay of capital, rob many workpeople of employment, and deprive the community of the benefits the commercial introduction of the article would have conferred.

"The refusal of patents for supposed lack of novelty imparts a false hall-mark upon the many invalid patents that are nevertheless granted, and so misleads the public.

"The proposed practice would place those seeking British patents at a disadvantage as compared with those seeking patents in other important manufacturing countries, such as France, Belgium, and Switzerland, where applicants are allowed to take patents at their own risk, and the United States of America, where the inventor is allowed, without prejudice to his rights, to use his invention for a considerable time before applying for a patent, and, therefore, stands a better chance of differentiating his invention from alleged anticipations; and where, also, if the examiner regards the invention as anticipated, the applicant can appeal to the Board of Examiners-in-Chief, and from them to the Commissioner, and from him to the Supreme Court of the District of Columbia.

"Official records show that during the past 45 years the subject has been often considered by eminent men and influential technical bodies, who have repeatedly expressed the opinion that an adverse report should not disentitle an applicant to a patent.

"In these circumstances we regard clause 7 as most dangerous and undesirable in the public interest,

and we, therefore, hope that it will be eliminated before the Bill becomes law.

Your obedient servants,

WILLIAM CROOKES.	ALFRED GORDON SALAMON.
HORACE DARWIN.	JAMES SWINBURNE.
H. S. HELE-SHAW.	JOHN I. THORNYCROFT.
WILLIAM RAMSAY.	

London, July 18th."

CARPET-MAKING IN BOMBAY AND BENGAL.

Two monographs on carpet-weaving in India have recently appeared, one dealing with the Bombay Presidency, and the other with Bengal. As, however, the former is the more important work of the two, it claims prior mention. The author is Captain H. J. R. Twigg, Superintendent of the Central Prison at Hyderabad (Sind), where the work of carpet weaving is actively pursued. The object of the monograph is to give an account of this industrial art in the past, the conditions under which the craft now exists, the current methods of manufacture, the improvements, and probable future of the industry. Of course it will be understood that the term "carpet" must not be construed too rigidly, and the question "When is a carpet not a carpet?" is not very easy to answer. The old Persian carpets were often so delicate and light in texture that not even stockinged feet were allowed on them. Many of these articles were used as *portières* or wall or ceiling decorations, or were spread over cushions. In Sind, what is called the *farasi* is usually spread on the bed, while among the free population of the Western Presidency, the very few articles made after the fashion or method of carpets are used for rougher and altogether different purposes. Indeed, it may be said that outside the jails, woollen pile carpets are practically not made at all. The pile, it may be explained, consists of the upstanding ends of very numerous pieces of wool woven in by hand into an understructure, generally of cotton. Such is the ordinary *galicha*, or pile carpet. The other common form of carpet is the *dari*, which is generally of cotton, and presents a flat surface and an identical design on both sides. The pattern is obtained by passing under and over certain cotton threads variously coloured pieces of yarn, the ends of which are broken off and the tags tucked in neatly. The pile carpets appear to have originated at an early date in Egypt and Babylonia, whence the art of weaving then spread westward along Northern Africa into Sicily and Spain. Eastward again, the numerous changes of rulership in the lands grouped round Persia has resulted in a mingling of characteristics in which trade routes and military camps played an important part. The *galicha*, as regards India, has followed Mohammedan advance, but how the *dari* has arisen in or spread throughout India is not known. Nevertheless the *dari* is more typically Indian than the pile carpet.

One important fact noted by the author is that exhibitions have in recent times played a prominent part in encouraging carpet-making in India. The origin of this movement was of course the Great Exhibition of 1851, previous to which only the connoisseurs had any knowledge of Indian carpets. Unfortunately a demand for cheapness and rapid out-turn soon arose, and this was succeeded by a deplorable falling off in excellence. Half a century later, the Delhi Exhibition of 1903 had a wholly good effect on the Indian carpet trade, and brought home to purchasers the general excellence of Indian carpets. A large proportion of those visiting the exhibition were American, and as America does not reckon carpets among its own products, a brisk demand from the States ensued for such goods as were not jail made, the latter being excluded by American Customs law. Those that were exported came usually from Amritsar, Lahore, Agra, and Mirzapur, but in addition to these there are scattered up and down the whole of India surprisingly numerous institutions, partly commercial, partly industrial, partly missionary or scholastic, which all send carpets to America. At the same time it should be borne in mind that some of the prison-made carpets have had an excellent effect on the artistic development of the industry. Sir George Watt is of opinion that the Poona Jail has been the means of distributing some admirable carpets over Western India, while the Yeraoda Jail has helped to conserve designs and fabrics which might otherwise have been lost.

The present work contains some fifty plates, which give a very pleasing and serviceable notion of the designs in favour in various manufactures. It is difficult to describe these, but the author remarks that many of them are mainly Persian in conception. Persian rooms are often long and narrow, and generally devoid, as most Eastern rooms are, of furniture. The guests thus recline on cushions, leaving the centre of the field open for careful inspection. To represent in such an area a flower-strewn field, unbroken by any predominating figure, was the Persian's idea of luxury in house adornment. European rooms, studded with articles of furniture, invite bolder treatment as a rule, for it is few people who would care to follow the example of Lord Clive, who, in order to set off one of his carpets to the best advantage, designed and fitted a special room for its reception. The quality of the work can be ascertained by counting the number of stitches to the inch, and how to do this is a task of some complication, explained at length by the author.

On the whole, the general history of the carpet-making craft in the Bombay Presidency has been a period of decline with regard to both *daris* and *galichas*. As already remarked, the Great Exhibition of 1851 greatly stimulated the demand, but in Western India more particularly, there has been a subsequent

deterioration, mainly if not entirely through the strong demand for a cheap article. The author seems to make good the point that it is not the jails that have undersold free labour, for it is estimated that a Bhubak (Sind) carpet costing Rs. 18, if made in the Shikarpur (Sind) Jail would cost Rs. 42. There is an enormous demand from America, and probably one-half of it is for rugs about 7 feet by 4½ feet, at a price of about Rs. 40 (£2 13s. 4d.) apiece. The demand for such goods is almost unlimited. Of course there is plenty of competition from Asia Minor and Persia, to say nothing of centres within India itself, such as Amritsar, Lahore, Agra, and Mirzapore. Both the United Kingdom and Germany, too, send carpets to India in gradually increasing numbers, the German product being mostly of inferior quality. The only remedy that the author sees for this state of things in Western India is to try and start a wool-producing area in Bombay, where a *dari* factory and organised agencies for export would probably flourish. Persia and Kashmir exclude aniline dyes, but if this exclusion were practiced in India, the cultivation of other dyes would have to be extended.

In Bengal, according to Mr. N. G. Mukerji, Assistant Director of Agriculture, carpet-weaving is of very minor importance. The total number of operators, including the dependent members of families who subsist on it, is less than 5,000, by far the greater proportion of these being connected with the cotton-weaving industry. In this province the carpet-weaving establishments of jails might be looked upon in the light of schools, were it not for the fact that discharged prisoners never take to the industry, and the teaching is thus largely thrown away. They have not the capital to start on their own account, and it would be well if a company or association were formed to further their employment after their release. At Patna, where a readjustment of the art has been effected, the weavers are in a flourishing condition, but elsewhere most of the district reports are pessimistic in tone. Some practical suggestions for improvement are made by Mr. Mukerji, the chief of them being that establishments should be founded in important centres like Calcutta, Dacca, Darjeeling, &c. The Government would be well advised apparently in taking steps to encourage these recommendations.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department, Admiralty, in June, 1907:—

New charts.—No. 3635—Norway:—Skarholmen to Sörholm. 3618—British Columbia:—Moresby passage to Gabriola pass.

New plans and plans added.—No. 3138—Anchorages in south-east Alaska; plan added:—Redfish bay. 3145—Andaman islands:—Port Anson, &c.; plan added:—Elphinstone harbour. 895—Eastern archipelago; plans of anchorages in Bali, Lombok, &c.; new plan:—Chanjar road.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners.

1607—England, east coast:—North Foreland to the Nore. 3191—England, east coast:—Woolwich to Erith. 2810—Ireland, east coast:—Lough Carlingford entrance. 122—Netherlands:—Mouths of the Maas. 3142—Netherlands:—Hook of Holland. 326—Denmark:—Great Belt. 2364—Germany, north coast:—Lubeck bay and Fehmarn belt. 449—Mediterranean sea. 689—Spain, south coast:—Gibraltar harbour. 1434—Adriatic:—Gulf of Trieste. 3119—Africa, north coast:—Alexandria harbour. 3301—Africa, north coast:—Tenez road and harbour. 2555—Africa, north coast:—Port of Algiers. 266—United States, east coast:—Great Egg harbour to Albemarle sound. 762—West India islands and Caribbean sea, sheet II. 2430—British Columbia:—Queen Charlotte islands and adjacent coasts of British Columbia. 2453—British Columbia:—Brown and Edye passages. 2563—Alaska:—Port McArthur to Windham bay. 2462—Alaska:—Windham bay to Icy cape. 2454—Phillippine islands:—Northern portion of the island of Luzon, &c. 1592—China, north-east coast:—Yung river and approaches. 624—Australia, south coast:—Hobson bay and river Yarra. 1512—New Zealand:—Anchorages on and off the north coast of North island. 2525—New Zealand:—North island, sheet I. 2460—Pacific ocean:—Kamchatka to Kadiak island, including Bering sea and strait.

These charts are issued by Mr. J. D. Potter, 145, Minories.

BAMBOO SAP.

The United States Consul-General at Calcutta says that the sap of the bamboo is used for medicinal purposes in India, and it may be had in the Indian bazaars at from one shilling and eightpence to five shillings and sixpence per pound, the latter being the specially white and calcined "tabasher." "Tabasher," or "banslochan," is sold in all Indian bazaars, as it has been known from the earliest times as a medicinal agent, its use as such having, it is supposed, originated among the aboriginal tribes. It is known in Borneo, and was an article of commerce with early Arab traders of the East. Its properties are said to be strengthening, tonic and cooling. A great deal has been written about "tabasher" in Hindu medical works which have been reviewed by modern writers. It has been analysed and has been shown to consist almost entirely of silica, with traces of lime and potash. With our present knowledge of medicine such an article is not calculated to be very efficacious, but from its remarkable occurrence in the hollow of bamboos the eastern mind has long associated it with miraculous powers.

HOME INDUSTRIES.

Motor Omnibuses.—It has been mentioned in these Notes more than once that it is still very doubtful whether, under present conditions, motor omnibuses can be run in the streets of London and other large towns at a profit. The question is an important one, for the success of the motor omnibus would be a serious matter for those corporations which have—as in London—invested immense sums belonging to the ratepayers in electric tramways. It is too soon as yet to express a confident opinion as to the financial possibilities of the motor car, but, as matters stand, the evidence points to loss rather than profit, any way in London. Only recently four motor omnibus companies were amalgamated under circumstances which left much to be desired. Another has had a meeting of shareholders this week at which the admission had to be made that all the subscribed capital has been spent, with little to show for it. The companies complain that their embarrasments are largely due to vexatious interference on the part of the police authorities, who insist upon expenditure that is unnecessary, and restrictions that are indefensible. But that is an *ex parte* statement, not to be accepted without reserve. That the motor omnibus is of great convenience to the travelling public where electric tramways are not available will hardly be disputed, but it is equally indisputable that the noise and smell which accompany them constitute a public nuisance, which has seriously depreciated house property in many districts, and is the cause of much personal annoyance in all. It is pretty safe to say that these grave drawbacks to the multiplication and even continuance of motor omnibuses will be overcome in time. It is claimed by some of the companies that they are already overcoming them. If and when that becomes true of the ordinary vehicle a great extension of this method of transport may be expected. It is said that, apart from the objections which make a section of the public the enemy of the motor omnibus, it cannot be run at a profit at present rates of carriage. If that be so, and there would seem to be ground for the conclusion, the companies may be expected to come to some working agreement under which fares will be raised. Negotiations having this object in view have been proceeding for some time, and the public will pay a higher fare rather than return to the horse vehicle. But it is indispensable that the objections to these vehicles due to their noise and smell shall be grappled with if they are to be left free to select any route that pleases them.

Docks and Steamers. — One of the strongest arguments in favour of the immediate deepening and improvement of the Port of London is that without it the great ocean steamships will not be able to use it since the draught of water they require is constantly increasing. The same difficulty is being experienced elsewhere. For example, the Cunard Company are seriously concerned at the state of things at New York as it effects their two great steamships, the *Lusitania* and *Maritania*. Dredging operations were begun in New York harbour some six years ago, and it was expected that the work of making a channel 35 feet deep at low water and 1,000 feet wide would have been finished last January. But in America, as elsewhere, delays have to be reckoned with, and it is now said that the new waterway will not be ready for another year at least. Meantime, and putting aside the *Lusitania* and *Maritania*, there is said to be at least a dozen liners entering the port of New York that cannot load to their full cargo capacity. At high water the passage is so risky, even for vessels drawing 30 feet, that owners prefer a loss in freight to the chance of their vessels going aground. The Government dredgers are said to be too small, ill adapted for the hard spots, and not powerful enough. It is a little surprising that the New York port authorities are backward in a vital matter of this kind, but the harbour authorities of most of the great ports of the world have, for one reason or another, failed to keep pace with the developments in ship construction. It means, of course, large capital outlay not always easy to arrange, and so postponed much to the inconvenience and loss of shipowners.

The Shipbuilding Industry.—The Board of Trade returns of the output of new ships in the six months ended June 30th last shows a large increase upon the corresponding period of last year, which itself was exceptionally large. In the six months exports numbered 764 vessels of 319,740 tons, valued at £5,571,847, as against 500 vessels of 209,180 tons, valued at £5,811,192 in the corresponding month of 1906. The decrease in valuation notwithstanding the large increase in output is due to the larger tonnage of war ships exported last year, and this makes the increase of merchant steamers all the more remarkable, the figures being 290,906 tons as against 185,505 tons in 1906. The figures here given relate to new vessels only. They do not include sales of second-hand steamers to foreigners. Also the launches and exports of the six months represent contracts booked in the early part of 1906, and probably include some booked as far back as 1905. They are no index to the new business of the present year. Nor is all the new tonnage as yet in commission. It represents the hopes of 1905-6 rather than the realities of 1907. The trade is less active than it was notwithstanding demands for increased wages. There are vacant berths in many yards. Lloyds' returns show that at the end of June there were 564 vessels "under construction" in the United Kingdom, of a united tonnage of 1,250,318 tons. These figures exclude war ships, and "under construction" includes vessels which have been long in the water though stiil in the builders hands, as well as those on the stocks. It must be taken, therefore, that the 1,250,318 tons includes much of the tonnage which figures among the launches of the present year. The total is less by 56,000 tons than the corresponding total at the end

of March last, and 160,000 tons less than the corresponding total at the end of June, 1906. Lloyd's figures show that there has been considerable shrinkage in the amount of the work in the hands of the shipbuilders; the largest decline being on the Tyne and the Clyde. Nor have new contracts been booked of late to make up for this decrease. It is said that in Scotland the new orders, booked in June, represent only 36,000 tons, as against some 65,000 tons launched. Low freights, high prices of material, increased cost of labour, all militate against new shipbuilding contracts. The shipbuilder was compelled to advance his quotations, and naturally the shipowner has put off as long as possible giving new orders. The prospects of the freight markets have not encouraged him to pay higher prices, and there was the probability that the demand for the raw material of the iron and steel industries would slacken and so enable the shipbuilder to reduce his quotations. It must be remembered too that the new tonnage now in the water is very large, and it would seem to be in excess of the carrier's requirements. On the whole it it is probable that the shipbuilding industry will not be very active during the remaining months of the year.

Cotton Profits.—If the figures given by Mr. William Tattersall in his cotton trade circular are accurate, cotton trade profits for the last half year were exceptionally large. He gives a list of 37 cotton spinning companies which have just taken stock for the six months, and the figures show at the rate of 40 per cent. per annum on share capital, or 30 per cent. on all capital employed. The total share capital is £1,451,741, and loans £514,129. A result of the continued prosperity of the cotton industry is that it is intended to "play" for a week longer this summer, so as not to overload the market. The reports as to the cotton crop are much more favourable owing to the improvement in the weather, and an output of 13,000,000 bales is now expected in some quarters, but the Department of Agriculture at Washington does not as yet support the most sanguine expectations. It made the improvement during June only 1½ per cent. Other reports have put it from 4 to 6 per cent., but even then have left the figures below the previous low record for July 1900, when it was 75·8. Although the weather has generally improved, it is said to have been so hot and dry in Texas as to cause fears that drought may be threatened in that State, where the plant is generally small, and the stands are rather poor. It would seem that at least, so far as this State is concerned, unusually good weather is required from now onwards, with a late fall, if serious shortage in the crop is to be avoided. Given good weather for the rest of the growing season an average crop may be gathered, but at present the probabilities seem to point to its being somewhat below the average. On the other hand the demands of the world's trade continue to increase, and possible shortage of the raw material in America will hardly be made up elsewhere. In this connection it is interesting to note that the Co-operative Wholesale Society, Limited, which represents in a special degree the cotton operatives of Lancashire, has invested £2,000 in the British Cotton Growing Association, whose object is the securing of a constant and sufficient supply of cotton from within the British Empire.

The Beneficial Effect of Prosecutions.—In her report to the Chief Inspector of Factories, Miss A. M. Anderson directs attention to what she considers the great benefit of successful proceedings taken against employers who have contravened the law notwithstanding every opportunity of knowing its provisions. She quotes to endorse the opinion of Miss Vine, another lady inspector, that no method of administration is so fruitful in good results in a district as a successful and widely-reported prosecution, at a hearing at which the magistrate has not only imposed heavy penalties, but also strengthened the inspector's hands by a few serious words as to the quality of the offence, and as to the issues involved when the laws passed mainly for the protection of the physically broken members of the State are not adequately enforced. It does far more good, in Miss Anderson's opinion, than a hundred instructions and cautions. For instance, after prosecuting one large firm, employing thousands of workpeople, Miss Anderson found, on visiting on an early date several other of their factories, that not only had prevalent infringements been rectified, but that, in addition, other matters regulated by the law had received the careful attention of the firm in question. The same thing is said to happen with reference to other factories under different management, situated in the same district. The day after another successful prosecution, in connection with which the magistrate's words in cautioning the defendants had been widely reported in the newspapers, on visiting other factories in the neighbourhood, Miss Anderson found all the employers unusually keen in carrying out the regulations of the Factory Act, one large firm having that morning sent for a plumber to remedy defects which, so far as Miss Anderson could judge, had existed for many months, simply because they had seen in the papers the account of the prosecution.

OBITUARY.

DR. DUPRÉ, F.R.S.—August Dupré, Ph.D., Chemical Adviser to the Home Office since 1873, died at his residence at Sutton on the 15th inst. He was born at Mainz on the 6th September, 1835, and after attending the Polytechnic schools at Giessen and Darmstadt he studied chemistry under Bunsen at the Universities of Giessen and Heidelberg. He graduated Ph.D. at the latter university in 1855 and then

came to London, from which time he made England his home, becoming a naturalised British subject in 1866. In 1864 he became lecturer on chemistry at Westminster Hospital Medical School, a position which he held until 1897. As chemical adviser in explosives he took an active part in investigating the explosives found in London and elsewhere during the Fenian outrages in the early part of 1883. In conjunction with Sir Vivian Majendie he saved Birmingham from a great calamity by himself rendering secure the nitroglycerine found in Whitehead's factory, and arranging for its safe disposal. He was joint author with Dr. Thudichum of a treatise on the "Origin, Nature, and Varieties of Wines," and with Dr. H. W. Hake, of a "Short Manual of Inorganic Chemistry." He also contributed a large number of papers to the various scientific journals. He was elected a Fellow of the Royal Society in 1875, and a Member of the Society of Arts in 1896. He was President of the Society of Public Analysts in 1877-78.

GENERAL NOTES.

Cotton Seed.—In his report on the trade and commerce of New Orleans in 1906 (Cd. 3283), Mr. Consul Carew-Hunt refers to the expansion of the cotton seed product industry in recent years in the United States. Not many years ago very little use was made of cotton seed except as a fertiliser. Now the products obtained are some of the chief articles of export from the South to European countries. Denmark is one of the largest buyers of cotton seed meal and cake for her large dairy industry. The cotton seed product inspectors at New Orleans send in the certificates giving the quality, as also the analysis for protein and ammonia, for all cotton seed products shipped. Their decision is considered as official by the trade, and has much facilitated business in these articles. There are 45 cotton seed oil mills in Louisiana.

The Trade of Russia.—It may be gathered from Mr. Consul Thesiger's report on the foreign commerce of Russia and trade (Cd. 3283) in 1906, that the political unrest had much less prejudicial effect upon trade than was generally supposed. The business done by the various mills and factories of the St. Petersburg district was exceptionally good, only the Metallurgical Works suffering from a shortage of orders. The value of goods imported into Russia from the United Kingdom in 1906 amounted to £11,040,000, or £990,323 more than in the previous year. The exports were, however, less by £2,503,684, the diminution being almost entirely due to the decreased export of grain. New regulations have recently been drawn up and sanctioned by Imperial Order relative to the placing of orders for the Russian Government in Finland and abroad. Finnish works are to be considered on the same footing as foreign works in regard to Russian Government contracts, and they are no longer to be allowed to compete with native works. But, other things being equal, in cases where orders are to be given to other than Russian works, preference is to be given to Finnish. At the close of 1906 the deposits of the State savings bank was said to have exceeded £104,266,666, without taking into account interest to the amount of £3,125,000. In addition, there were in the savings bank at the end of the past year paper securities to the value of £24,583,333. During the last decade—1897-1906—the deposits more than doubled, while the paper securities increased more than five-fold. In 1905 there was a decrease in deposits of £11,083,333, but in the following year there was an increase of £17,656,250, which not only wiped out the decrease of 1905, but left a net increase of £6,572,917, as compared with 1905.

The Uganda Railway.—The extract from the report of the acting manager of the Uganda Railway published as an appendix to the report on the East African Protectorate for 1905-6 (Cd. 3285) shows that the railway is making satisfactory progress. The result of the year's working was a net profit of £56,878 compared with £2,639 in the previous year, and a dead loss of £60,100 in the year 1903-4. The gross receipts amounted to £204,928 as against £153,794 in the previous year, and £131,567 in 1903-4, an increase of 33·25 per cent., and 55·76 per cent. in each succeeding twelve months. The percentage of expenditure to gross earnings in the year under review was 72·34, against 98·29 in the previous year, and 145·68 in 1903-4. The steamboat service increased its earnings from £14,466 to £22,340. It did a business larger by 50 per cent. for the same money. Coaching traffic shows less improvement than earnings under goods and steamers, yet it has increased from £35,199 to £43,180 (some 22·69 per cent.), but the margin of profit is small—small, that is, for the country,—nor is it likely that any reduction would largely increase the numbers travelling, or induce a more paying business. "In the immediate future," says the Acting Manager, in his report, "it is a hard struggle for the pioneers, and although it may be encouraging to see rates for fibre, rubber, cotton, &c., lowered, yet (except where capital is behind them), the growers are sorely pinched by the high rates of many of the principal necessaries of life—flour, rice, sugar, &c., all of which are exceedingly expensive up country, due to the high cost of carriage." The Uganda Railway was not projected as a money-earning system; its aims are far broader—the development of a new country, and the smaller the surplus over the working expenses during the next few years the better. For some years, at any rate, a portion of the increased earnings will be used for the improvement of the line and the reduction of rates.

Journal of the Society of Arts.

No. 2,854. VOL. LV.

FRIDAY, AUGUST 2, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

FOTHERGILL PRIZE.

FOR LIFE-SAVING APPARATUS FOR USE IN NOXIOUS ATMOSPHERES.

The Council of the Society of Arts are prepared to award, under the Fothergill Trust, a Gold Medal, or a prize of £20, for the best portable apparatus or appliance for enabling men to undertake rescue work in mines or other places where the air is noxious.

It is intended that the apparatus sent in shall be submitted to practical trials and tests.

In the award of the Medal regard will be had, firstly, to excellence of design and contrivance, and, secondly, to excellence of manufacture. Credit will be given to such parts of the apparatus as are the invention of the exhibitor; the object being to distinguish the apparatus which gives the best promise of being practically useful.

Inventors intending to compete should send in a notice of their intention, together with a full description of their inventions, not later than 31st March, 1908, to the Secretary of the Society of Arts, John-street, Adelphi, London, W.C.; and in cases in which the apparatus has been put into actual use, the experience of such use should be given, and the special points of merit of the apparatus indicated.

Notice of the place to which the apparatus is to be sent will be subsequently given to those competitors whose apparatus the judges may desire to test, together with an indication of the tests, and of the manner in which they will be conducted.

Competitors intending to patent their inventions should be careful to obtain protection, as the Council of the Society cannot undertake any responsibility as regards the secrecy of the whole, or of any part, of an invention submitted to them.

The Prize will be awarded on the report of judges appointed by the Council.

The competition is not limited to British subjects.

The Council reserve to themselves the right of withholding the Prize, of extending the time for sending in, or of awarding a smaller Prize or smaller Prizes.

STOCK PRIZE.

FOR THE DECORATION OF PART OF THE INTERIOR OF A BUILDING.

The Council of the Society of Arts are prepared to offer, under the terms of the Stock Trust, a Gold Medal, or a Prize of £20, for competition amongst the students of the Schools of Art of the United Kingdom, at the Annual Competition to be held in 1908.

The Prize is offered for the best original designs for an Architectural Decoration, to be carried out in painting, stucco, carving, mosaic, or any other process.

This Architectural Decoration is to be for the side of a room or a hall, a ceiling, the apse or side of the chancel of a church, or any suitable part of the interior of a building.

The designs must be on imperial sheets. Each set must consist at least of a coloured drawing to scale of the whole design of decoration, and two coloured drawings of details on separate imperial sheets. Mere patterns or sketches of details, without the mouldings or borders necessary to make up a complete decorative scheme, will not be taken into consideration. The designs must have been made between 1st April, 1907, and 31st March, 1908.

The recipient of a prize awarded under this trust in 1893 or 1897 cannot compete again.

The designs are to be submitted, with other school work, in the usual manner, to the Board of Education, South Kensington, in April, 1908. Each of the imperial sheets, forming a set of competing designs, must be marked, "In competition for the Stock Prize," in addition to being labelled or staged according to the Regulations of the Board of Education.

PROSPECTS OF INDIAN MANGANESE INDUSTRY.

By A. Ghose, F.C.S.

According to the latest available official statistics the total import of manganese into the United Kingdom during the last year amounted to 490,612 tons with a declared value of £865,443. Of this India contributed 129 990 tons, valued at £359,925. The largest quantity from India was exported through Bombay, and the figure reached 92,700 tons of ore, mainly from the rich mines of Nagpur, Balaghat, and Bhandara districts of the Central Provinces, and from Jhabua State in the Central India Agency. From Madras 7,819 tons were exported to the ports of the British Isles. This represents a fraction of the output of Vizagapatam mines, most of which is consumed by Continental furnaces. Calcutta exported 20,370 tons, and as there are no important manganese deposits at present being worked in Bengal, it is safe to assume that the above quantity was derived from the mines of the Central Provinces. Through Marmagoa Harbour, in Portuguese India, 9,101 tons were shipped. This came from the Kumsi mines in the Shimoga district, Mysore State, and Ramandrug mines in the Sandur State, Bellary district.

The figures quoted above do not apparently present any striking facts as to the growth of the manganese industry in India. But when compared with the import of manganese from India in 1905 into the United Kingdom it becomes evident that the demand for Indian manganese has grown with extreme rapidity. In 1905 Indian export of manganese to Great Britain totalled 71,660 tons, and it is clear that last year's supply reached nearly twice the above figure. The most significant feature of the import of manganese into the United Kingdom is that India headed all the countries which supply the British furnaces with manganese ore, Brazil with 127,257 tons being second, Russia coming next with 103,276 tons.

From the above, it will be seen that India has attained a leading position in the world's manganese market. The total output of Indian manganese during 1905 reached 281,734 tons. This figure has been far exceeded during the past year, Bombay alone shipping over 310,446 tons, as the partial closing of Russian mines, the enhanced price and increased demand gave an impetus to the industry with the result that several important mines were opened, and large quantities were shipped from new localities.

The demand for Indian manganese ore for Continental furnaces is steadily increasing and the quantities shipped to Belgian and German ports exceed the export to England. The high grade ore of the Central Provinces even finds a market in the United States, and heavy shipments were made to the ports of Baltimore and Philadelphia during the past year.

The increase of the world's steel production is the key to the greater demand for manganese, and the supply is influenced by the partial failure of the Russian mines, hitherto the largest producer of manganese. Besides numerous railway extensions, and naval and engineering projects, the earthquakes of San Francisco, Valparaiso and Kingston have led to the placing of large orders for steel structures, and since the manufacture of ferro-manganese and speigeleisen depends on manganese, the demand is natural.

The stability of the Indian manganese industry and the extraordinary demand may be well gauged by the fact that some of the foreign consumers have already acquired or are negotiating for the purchase of manganese properties in India. It is said that a large deposit of ore in the Balaghat district, Central Provinces, has been secured for the Carnegie Syndicate. Another property in Mysore has passed into the hands of a German firm. These transactions form a convincing proof of the quality of Indian ore and the shortage of foreign supply.

An idea of the extraordinary demand may be formed from the fact that shipments have been made of ore containing as low as 33 per cent. of manganese metal. It is doubtful whether such inferior ore has ever before been exported from India. Inquiries have also been made for the purchase of manganiferous iron ore containing 30 per cent. manganese. The market conditions are such that the buyers have relaxed the standard of purchasing ore and are paying good prices even for low grade ore, which is thus able to bear the heavy sea freight in addition to mining and transport charges.

With the re-opening of some of the mines in the districts of Sharopan, in the Caucasus, and Nikopol, in the Donetz region, Russia is trying to regain her former supremacy in the manganese market. But so long as the provinces of the Caucasus remain unsettled, there is no likelihood of Russia largely increasing her output so as to bring about

a fall in the price. The fact is that some mine-owners and exporters at Poti and Batoum having broken their contracts by failure to deliver, the confidence of buyers in Russian ore is shaken, and it has been found much safer to rely on Indian producers. In this connection, some of the most prominent men actively engaged in manganese business paid visits to India this year to satisfy themselves as to the capacity of certain important Indian manganese mines and to place large orders with reliable shippers of ore, and several forward contracts for heavy consignments have been made.

The average percentage of manganese metal in ordinary Russian ore is about 50. The quality of the Russian ore is no doubt excellent, but sometimes the presence of an excess of silica and phosphoric acid places the Russian ore in a disadvantageous position in comparison with certain Indian ores which are low in silica and phosphorus, and thus better suited for the requirements of the smelters. The ore from the most important Russian mines of Transcaucasia—at Tschiatura, in the province of Kutais—mainly consists of pyrolusite, which is the softest ore of manganese. An idea of the softness of this ore can be formed from the fact that a single miner can extract over ten tons of ore in the course of a day simply by means of a pick-axe. Such pulverulent ore is almost unknown in India in workable quantities, except in some deposits in the province of Goa in Portuguese India. This softness of the Russian ore has an important bearing on the demand for Indian ore. The Russian pyrolusite and allied ores, when shipped and delivered at the smelters, are partly reduced into a powdered state, on account of which there is not only loss in the transit, which results in shortage of quantity, but a portion of the finely-reduced powder is further lost at the time of metallurgical treatment. On the other hand, the Indian ore, with its compact structure, hardness and friability, and comparative absence of dust ore, is easily handled, and is better appreciated by smelters. Thus it will be seen that, even if the Russian production is increased, the superior quality of the Indian ore in the above respects will find ready purchasers.

Brazil has long been a serious competitor of India in the manganese market. Although much of her ore is consumed in the United States, still the exports to Europe reach a high figure. The quality of Brazilian ore approaches that of the ore exported from the Central Provinces mines, the percentage of manganese in both being high sometimes containing as much as 55 per cent. It is an open secret that some of the important mines in Brazil, which have been worked for several years on a large scale, are exhausted, or are about to be closed. The principal mines are in Queluz district, in the State of Minas-Geraes, and in Bahia. The exhaustion of some of the deposits cannot impair the manganese resources of Brazil, as there are not a few deposits still unexploited. In the State of Matto-Grosso, near the Bolivian frontier, an extensive deposit has already been prospected. This deposit in Corumba has just been leased out to a Belgian company with a capital of 7,000,000 francs. It is favourably situated, being a few miles from Paraquay river, and will ere long begin shipment.

Of late much has been said in favour of the newly discovered deposits of manganese in Borneo, and in uninformed quarters it has been whispered that the working of these will seriously affect Indian manganese trade. But this apprehension is not founded on a solid basis. The quality of Borneo ore has been found to be low, and the silica content of this ore is above the ordinary trade requirements. Apart from the quality, the distance of Borneo is not favourable for securing lower freight for the ore.

It has been pointed out by an eminent authority that India is a loser by exporting raw manganese ore instead of ferro-manganese. It is true that the price of ferro-manganese is several times that of even the highest grade ore. But India is a country where everything moves slowly, and it is also the mine owners' "Land of Regrets" in not a few respects. In England there are large beds of iron ore almost side by side with seams of coal of high quality. By irony of fate it is just the contrary in India, where the existence of immense deposits of iron is synonymous with the entire absence of fuel. That is almost invariably the case with manganese also. It may be possible to smelt and reduce manganese ore either by importing coal, or by transporting manganese to the neighbourhood of Indian coalfields where facilities exist, and to export the product with profit. It is evident that in this way even the low grade ore, thousands of tons of which are wasted every year in India as unfit for shipment, can be profitably utilised. But enterprise is yet wanting in this direction.

Recently a proposal has been made to the

Russian Government to impose an export duty on Caucasian manganese ore. If this is given effect to, then it will stimulate the Indian manganese export. As the export of the ore to Continental and British ports is more profitable, it has been found difficult to get supplies of manganese for the furnaces in the south of Russia, and the difficulty has increased so much this year that a large number of furnaces are idle, and some of the most important steel works are closed. This fact is in strong contrast with the opinion of those who condemn the shipping of the raw ore from India instead of its conversion into ferro-manganese locally, which can certainly be exported with greater ease and profit. If in a European country, famous for its manganese production, where numerous furnaces already exist, it is found necessary to close many of them for shortage of supply because the export of the raw material is preferred, then what guarantee is there that if smelting works are erected in India, the supply of ore will be kept up, unless the mines and furnaces are controlled by the same agency?

A new era of mining activity and metallurgical industry is dawning upon India. We are about to see the opening of the long-talked-of largest iron and steel works in India, at Sini on the Bengal-Nagpur Railway. The re-opening of the vast belt of copper ore in the Singbhoom district may lead to the extraction of copper in the near future. The immense but long neglected deposits of aluminous laterite have been proved to be inexhaustible sources of alumina and hence of aluminium by the Indian Geological Survey and await development and utilisation. The establishment of metallurgical works for the manufacture of ferro-manganese is only a question of time and capital. In this connection it is interesting to note that the Government of Mysore specially deputed Dr. Smeeth, the head of the State Geological Department to Scandinavia, to visit the centres of electro-metallurgical industry there. Recently the Secretary of State for India placed Mr. Holland on special duty in Europe, and one of the questions studied by him relates to the manufacture of ferro-manganese and spiegeleisen in India. The reports of the above officers which must contain vastly important informations are withheld from the public probably pending the decision of the authorities concerned.

An instance of what can be achieved by the conversion of water-power into electricity and its employment in smelting may be cited here, although the electro-metallurgy of manganese is not yet in a very far advanced stage. In the south of France, in the Pyrenees, there are veins of rhodonite, a silicate ore of manganese (which is thrown away in some of the Nagpur mines) which on account of extremely high percentage of silica and low metallic manganese content cannot bear the cost of transport. But the proximity of these deposits to waterfalls has led to the electro-metallurgical reduction of this ore and the product is exported with much profit. In India, except in Goa and near Munsar in the Nagpur district, waterfalls are not known to exist in the vicinity of manganese deposits. The low quality of Goa ore will well-repay the electro metallurgical treatment. Perhaps it remains for the Government of Mysore to take the lead in the preparation of ferro-manganese in India, which if accomplished even on an experimental scale, will result in the establishment of larger works. It is hoped that the third installation in the Cauvery Falls power station recently undertaken, which will develop an additional 2,700 British horse-power under a fall of 380 feet, will afford means for demonstrating that ferro-manganese can be prepared with advantage locally. The harnessing of the Niagara Falls has led to the establishment of most important electro-metallurgical works on both the States and Canadian sides. But in India, the immense falls of Gersoppa still remain unexploited.

The disorganisation of the Russian manganese industry has led to vigorous ef[illegible]rts bei[illegible] have undertaken in order to find a s[illegible] 33 per manganese in the Bessemer o[illegible] [illegible]ubtful carbonising iron. An addition of [illegible] salt followed by small quantities of coke thrown into the molten metal, has been found to facilitate this operation, and this treatment has been tried with success at Homecourt. This process does not dispense with the use of manganese, the quantity of the ore ordinarily used in the operation being only reduced. India, with her inexhaustible deposits of ore, has not so much to fear from the competition of other manganese-producing countries. But it is probable that, at some distant date, the manganese industry may be completely displaced by the discovery of some artificial means as a substitute for manganese in the manufacture of steel, and to this end not a few chemists and metallurgists are labouring. But the accomplishment of this will take

several years, and manganese miners need not be alarmed at present.

The export of pyrolusite, the dioxide of manganese, for the manufacture of chemicals, has not yet taken place from India, although this ore has been met with in some places. There is a remarkable deposit of this in combination with other manganese ores at Pali, about six miles from Munsur, Central Provinces. The ore has yielded 62 per cent. of manganese. Pyrolusite is often met with in Goa deposits in quantities worth exporting. As the price of pyrolusite is much higher than that of the ores used for the metallurgical purposes, it is worth while for those who find it in sufficient quantity to sell it to the manufacturers of chemicals. But for this, the trade requirements are such that only pyrolusite of high purity can be sold. For the use of glass manufacturers, it should be free from iron. The utility of manganese in glass manufacture consists in its peculiar property of discharging the brown and green tint due to the presence of iron in the sand. This is why the French call this variety of ore—"le savon de verriers." For the manufacture of chemicals such as bleaching powder, the ore is sold on oxygen value basis, and should be free from iron and lime compounds to prevent the unnecessary waste of acids. But the presence of silica is not objectionable. Japan is at present one of the chief producers of pyrolusite, and during the last year, 320 tons, worth £800, were exported to the United Kingdom by that country. A quantity of pyrolusite has recently been exported from a Cape deposit. Owing to its softness and brittle nature, this ore is conveyed in bags. The utilisation of the bye-products of coke manufacture by the introduction of recovery ovens in the Giridih coalfield marks a distinct advance in the chemical industry of India. The local manufacture of chemicals in which manganese plays an essential part, is also a subject worthy of serious consideration in India.

Although the Geological Survey of India published long ago notes on some manganese deposits in India, and Ball in his monumental work on "Economic Geology," noticed some of the principal deposits, still the importance of working them was hardly realised, and it was left entirely to private enterprise to start the manganese mines in Vizagapatam district, in the Madras Presidency, and the Nagpur, Balaghat and Bhandara districts in the Central Provinces. The pioneers of the industry in the above-named districts cannot be sufficiently praised for their bold venture, as they discovered and started the mines on their own initiative, in spite of scanty reports and encouragement. On the other hand, it is curious that the Geological Survey records contain an exhaustive report on the deposits of manganese in the Jubbulpur district, in which the value of these deposits has been specially pointed out; but these deposits still remain practically untouched, as they cannot compare in importance with other great Indian deposits, which were mostly discovered through the efforts of private individuals whose names remain unrecorded. Active interest in manganese deposits taken by the Geological Survey of India properly dates from the appointment to the directorship of Mr. T. H. Holland, F.R.S., that distinguished geologist who has done so much for the promotion of Indian mineral industry. The researches with regard to manganese deposits, inaugurated by Mr. Holland and ably conducted by Mr. Fermor, may appear to a certain class of men as mere scientific speculation, with a view to add some more names to the already long list of minerals, economic and otherwise. It is needless to say that such views fail to appreciate the importance of scientific investigations, specially those directed to unravel the origin of manganese deposits. These researches are likely to lead to the identification of manganese-bearing rock series in still unexplored parts of India, as it is more than certain that a great many manganese localities in India still remain undiscovered.

The manganese quarries of Vizagapatam district have been worked for about ten years, and some of them have approached exhaustion. The situation of these deposits is excellent on account of the proximity of a sea-port, and this has resulted in profitable exploitation of a middle-grade ore, containing high percentage of phosphorus, suitable for the basic process. The important mines of the Nagpur district in the Central Provinces are mostly situated in the neighbourhood of Kamptee, and the ore produced in that locality is of the highest grade so far exported from India. Only sometimes the percentage of silica exceeds the limit of standard requirements, a disadvantage evidently due to the preponderance of braunite in the ore of this locality. The deposits at Ramtek, Munsur, Kachurwahi, Manegaon, and Kodaigaon, are all noted among others for the excellence and abundance of ore, mainly an intimate mixture of braunite and

psilomelane. The newly opened mines in Bhandara and Balaghat districts are said to show extraordinary development of ore bodies, and are being actively exploited, several light railways being built to ensure heavy export. The deposits of manganese in the Chindwara district, on account of transport difficulties, are in a disadvantageous position in spite of the richness of the ore. A deposit is being worked with success near Meghnagar in Jhabua State, Central India Agency. The comparatively unimportant superficial deposits of manganese ore in the Jubbulpur area, and in the neighbourhood of Chaibassa in Bengal, are also being worked on account of the prevailing high price of the ore. In Mysore, Shimoga, Chitaldrug,, and Tumkur districts, are pratically in the hands of manganese exploiters, hundreds of miles having been taken up under exploring or prospecting licenses. A large quantity of good ore consisting of psilomelane has been exported from the boulder beds in the neighbourhood of Kumsi which are being worked extensively, and new deposits are being opened out in the Shankargudda Range, and in the Tumkur, and Chitaldrug districts. In the Sandur State in the Bellary district mining operations are proceeding on a large scale; the ore of this locality being non-silicious and non-phosphoric is in great demand. In Portuguese India the craze for manganese has reached its highest limit, and the speculative element is at its maximum. The deposits are all in laterite, and although there is a considerable quantity of good ore, the life of the majority of the deposits is limited, only few of them being of commercial importance. Among these are the mines at Sancordem, Candiapar, Fanuswadi, and Wagy; from these mines export has taken place. The proximity of Marmagoa Harbour affords exceptional facilities for working with profit even an inferior quality of ore. There are isolated manganese localities near Talewadi and Khanapur, in the Belgaum district. Deposits have also been found in the Kristna district.

The search for new localities is being conducted so vigorously that it evokes admiration, although the ignorance of the majority of explorers and their patrons leads to the exploration of barren tracts where the chance of finding manganese is remote. However, this is an indication of an awakening interest and recognition of the possibilities of the mineral resources of the country. The construction of the railway line between Raipur and Vizagapatam will bring to light not a few metalliferous deposits in that area, as it is presumed that the manganese-bearing rocks of the Central Provinces extend into the country to be traversed by the railway under construction. Dr. Walker, late of the Geological Survey, noticed the existence of manganese in the Kalahandi State, and there is reason to suppose that there are several out-liers between Raipur and Vizagapatam which deserve exploration. Manganese has also been found in Kalicotta and Kalahasti State. The Dharwar rock series in Mysore and the Bombay Presidency should receive special attention, as this formation is the most important repository of manganese ore in Peninsular India.

The scarcity of the ore, and the consequent high prices, have led to active exploration for manganese all over the world, and have resulted in the finding of numerous new localities, most of which are unimportant. The search for manganese has even penetrated into the polar regions. Promising deposits have been found in South Africa and St. Helena and some of the abandoned deposits in England are being reopened. The discovery of a number of payable deposits in other countries and the reopening of Caucasian mines will in all probability lead to over-production. Even in India the tendency is in that direction and a shortage of supply of wagons on the railways concerned with manganese traffic is a mere question of time. It is probable that the deposits in the Sandur State and also some in Mysore, on account of their immense reserves of ore and nearness to the sea, may take an important part in the world's production, and Marmagoa harbour is likely to surpass other Indian ports in manganese export in the near future. But the present capacity of that harbour is extremely limited, and unless this is promptly remedied the South Indian manganese industry will receive a serious check. The over-production of ore in India and elsewhere is greatly to be feared as this is bound to influence the market and will result in the reduction of the price. A combination of all the important mineowners of India could have averted the competition to a marked extent. But, unfortunately, this is almost out of question. The day of artificial substitute is not yet, and so long as there is no over-production India's present position in the world's manganese market may be regarded as safe.

WIRE ROPEWAYS.

This form of modern transport is one which is developing rapidly, and as it works absolutely mechanically, and at a comparatively small original cost, it provides a cheap and economical means of conveyance. The advantages of the system are fully recognised by experts, and it naturally follows that its employment is increasing in all parts of the world. To-day, ropeways of very great length come well within the region of possibilities, and neither the difficulties of the ground nor the influence of the weather offers any serious obstacle to their erection. It may, in fact, be safely said that in many cases—for instance, when it is a question of systematically opening up mineral treasures in steep and unapproachable mountain regions—this means of transport is absolutely without competition. The working of the enormous and rich lodes of copper in the South American Corderillas, which, on account of their inaccessibility, lay either untouched or were at least very inadequately worked with the inefficient means of transport available, could never have been entertained without recourse to the railway through the air, as a railway track may be considered as an impossibility at heights ranging to 6,000 metres.

The most perfect picture of the modern wire ropeway is no doubt the unique ropeway built some little time ago by Messrs. Adolf Bleichert and Co., Leipzig-Gohlis, in the Argentine Andes, and which, running from the town Chilecito to the Famatina Mines, at a height of some 4,600 metres above the level of the sea, may be said to form a continuation of the State railway. This wire ropeway, a masterpiece of engineering, is not only the most elevated railway plant in the world at its upper end, but nowhere else has a steam-engine ever been erected at such an elevation as here. The track has a length of about 35 kilometres with a difference in level between the two terminals of about 3,500 metres, and is in other respects the most difficult plant of this description which has ever been built and put in work. It must not be forgotten that this ropeway has to deal with general traffic. Not only is the ore brought down from the heights to the railway and the smelters, but all building material for the mines and the necessaries of life for the workmen must be carried up. It is also employed for carrying the mails, and the officials even use it for passenger traffic. The introduction of this plant with a capacity of 40 tons down traffic, and about 20 tons up traffic, reduced the cost of transport from something like 50s. per ton to about a tenth of this sum, and thus rendered it possible to compete on a large scale in the foreign market. The success which this plant has attained has led to the erection of further Bleichert ropeways in the neighbouring mines in Argentina, as also in Chile. Very similar conditions rule in Japan, where the same firm has also built several important and difficult plants for working copper mines in mountainous regions. These are several kilometres long, with considerable differences in level, so that with their spans of from 400 to 600 metres they may well be ranked with the Argentine ropeway.

In conclusion, the employment of this transport system in connection with loading plants must not be forgotten, whereby landing stations on otherwise inaccessible coasts have been made possible. In such cases wire ropeways can again be said to be indispensable, as no suitable substitute can be found. The plants carried out by Messrs. Adolf Bleichert and Company on the coast of Spain, on the island of Elba, and in New Caledonia, which have capacities up to 250 tons per hour, prove conclusively that there are no limits to the employment of wire ropeways, and neither ground nor harbour conditions can offer insurmountable difficulties to the erection of such means of transport.—*World's Carriers.*

THE MINT.

The report of the Deputy-Master and Comptroller of the Royal Mint directs attention to the increase in the loss per million sterling on the gold coinage. This loss is almost entirely due to the inferior quality of much of the gold bullion received. The presence of the impurities which cause the brittleness is not detected by the ordinary test made by assayers, and is not revealed until the bullion sent for manufacture has been standardised by the addition of copper. Until 1870 the Master of the Mint had the right to reject gold bars found brittle in the process of coinage, but in that year, as the result of certain experiments, this regulation was rescinded. The new arrangement worked fairly well until 1899, when a considerable number of ingots refined from rough bullion originally produced by the cyanide process were imported. Since that date difficulties from brittle gold have occurred in 1902 and 1903, and the large proportion of this gold delivered for coinage last year raises the question in a very different and serious form. The Deputy-Master writes:—

"It may be assumed that the employment of the cyanide process is now largely established; that the ordinary process of refinement by sulphuric acid as practised in London gives unsatisfactory results in dealing with impure gold under modern conditions; and that this department is not provided with any means for economically purifying defective gold. The consequenee is that loss of time, grave public inconvenience, and additional cost, is incurred in the coinage of gold. These disturbing elements are not inevitable. Brittle bars are, I believe, quite unknown in the new mints of the United States, and in those of Australia, and the process of refining which it is proposed to instal in the new branch mint at Ottawa will, it is believed, ensure equally satisfactory results there. It remains, therefore, to be seen whether the process generally used in London can be so improved

as to cope efficiently with the impurities left by the cyanide process."

Referring to the same matter, Mr. Edward Rigg, I.S.O., Superintendent of the Operative Department of the Mint, says that the experience of the year has clearly demonstrated that when gold giving sound malleable bars is melted with copper to produce standard metal, the normal loss does not exceed two ounces per 10,000, corresponding to the average loss incurred in former years, but when the gold referred to above is similarly standardised it produces bars of varying degrees of brittleness, often so marked that the bar cracks in pieces on being struck lightly with a hammer, and is at the same time characterised by a largely increased melting loss—often nearly double the above amount.

SCIENTIFIC RESEARCH IN INDIA.

Amid the crowd of official reports produced in India there are many of general interest, deserving of note in this country. The "Report of the Board of Scientific Advice for India" is an annual of recent origin, but nevertheless appears to be destined to play an increasingly important part in the economy of the country. The Board itself was originally constituted in 1902, and consisted of the heads of the Meteorological, Geological, Botanical, Forest Survey, Agricultural, and Veterinary Departments, the Government reserving power to add other officers of special attainments as need might suggest. It was to be a central authority for the co-ordination of official scientific enquiry and for aiding the Government of India in questions of economics and applied science. Fresh officers have since been added to the Board, and from the Report for the year 1905-6, which is just to hand, the field of discussion and research would seem to be very wide. "Economic and Industrial Chemistry" records a variety of experiments in regard to india-rubber, resins, oils, dyes and tans, and medicinal substances. One of the most curious of these relates to a report of Messrs. D. Hooper and H. H. Mann on no fewer than 33 samples of edible clay, which they submitted to analysis. There is no food value in these earths; nevertheless they are commonly sold in the bazaars, more especially in times of scarcity. In the Bombay Presidency cimolite is baked and eaten, and hydrated silica in Madras and Travancore. Palia stone of Rajputana, consumed in time of dearth, is really talc schist; most of the other specimens are mixtures of sand and clay.

Passing by observations on solar physics, magnetism, and meteorology, which pertain rather to the domain of specialised science, note may be made of an interesting account of the mineral developments of the country. The total value of the minerals raised for which trustworthy returns are available increased from £5,357,840 in 1904 to £5,707,956 in 1905, while the number of licenses for exploring, prospecting, and mining issued rose from 151 to 189. The greatest activity in prospecting was shown in the Central Provinces, where manganese is the principal mineral sought for, and in Madras, where gold and mica received most attention. Gold dredging concessions granted on the Chindwin and Irrawaddy rivers and on the Nam-ma stream in the Northern Shan States were visited, and a report on them is now under the consideration of the Government of India. The ancient silver-lead mines of Baudwingyi to the east of the ruby mines, which were worked on a large scale by the Chinese up to the middle of the last century, were also reported on. Active exploitation of these mines is now in progress. The diamond mines of Panna State in Bundelkhand are also mentioned. The methods of working the deposit are very primitive, either by pits or shallow workings. The principal source of the stones is a conglomerate separating the Kaimur sand-stones from the Rewar shales, and they are considered to have been derived from the granite area of Bundelkhand.

In the domain of geography, Lieut.-Colonel S. G. Burrard, Superintendent of the Trigonometrical Survey, contributes two interesting papers to the Report. The first of these deals with the region of Seistan, near the tri-junction of the three States, Persia, Afghanistan, and Baluchistan. A great deal of information about Seistan has been acquired during Sir H. McMahon's recent Mission by Mr. G. P. Tate, of the Survey of India. Mr. Tate, who had much previous surveying experience in Afghanistan and Baluchistan, carried out a topographical survey of 42,000 square miles on the scale of 4 miles = 1 inch, and of 3,000 square miles on the scale of 1 mile = 1 inch. He is now preparing two maps and memoir, the latter with certain accounts of the ancient and present topography of Seistan as well as notes of its archæology and ethnology. The country of Seistan is formed by the delta of the Helmand, and supports a population of 105,000; it is comparable to the deltas of the Oxus, Jaxartes, and Tarim rivers, which also deposit their waters in inland lakes. Mr. Tate found that the Seistan lagoon was nowhere deeper than 10 feet; he estimates its area at 2,000 square miles. In the arid climate of Central Asia a quarter of an inch depth of water will be evaporated daily from an exposed surface, and it can be thus realised how rapidly the Seistan lagoon would become dry if the supplies from the Helmand ceased. The question still remains in the constant struggle that is going on between sand and water with which of these elements the victory will ultimately rest? In the case of the Seistan oasis, Colonel Burrard thinks that the sand is increasing while the water is not, so that the former must in the end prevail.

As regards the exploration of the Brahmaputra (which it may be remembered was recommended by the Royal Scottish Geographical Society) Colonel Burrard makes some suggestive remarks. He draws attention firstly to the curious

tendency of all its principal tributaries to flow in a direction opposed to that of the main stream, and deduces therefrom the inference that the Brahmaputra itself flowed from east to west along its present trough at no very distant date, and that the several tributaries were developed during that period of the river's history. If so the present passage of the river across the Himalayas into Assam in longitude 94° must have been formed under circumstances of extraordinary interest and mystery. The explanation suggested by Colonel Burrard is that the Brahmaputra, when it reversed its course, formed a great lake in South-Eastern Tibet, which overflowed over the southern ranges, and gradually cut a gorge across them. An interesting phenomenon of Himalayan geography is that where a deep gorge is thus formed by a river, the highest point of the range is often, if not generally, found in close proximity. For instance, Nanga Parbat, the highest point of the Punjab Himalaya, is fourteen miles from the gorge through which the Indus passes the range; Rakhi pushi, the highest point of the Kailas range, is within nine miles of the gorge of the Hunza river; Daulagiri is six miles from the Kali-Gandak; in escaping from Tibet the Sutlej appears to aim for the peak of Leo-Porgial, the highest point of the barrier range. Colonel Burrard offers no very confident solution of this curious feature, but there is no doubt that it would be peculiarly interesting to test by actual exploration whether the same phenomenon exists in the neighbourhood of the branch formed by the Brahmaputra through the Eastern Himalayas. The region in question is, however, a *terra incognita*, so we shall probably have to wait for the investigation of this physical problem.

HAND-LOOM WEAVING IN INDIA.

During the past twelve months the reorganisation of the hand-loom weaving industry has made considerable progress in the Madras Presidency, chiefly in the direction of establishing hand-loom weaving factories equipped with fly-shuttle looms. The most important of these factories is that established by the Government of Madras, under the direction of Mr. A. Chatterton, Director of Industrial and Technical Enquiries in the Madras Presidency, at Salem, where between 40 and 50 looms are at work, and where experiments are in progress to test the relative merits of different patterns of looms.

So far (says the *Indian Trade Journal*) no loom has been discovered by Mr. Chatterton that is superior for all-round work to the English hand-loom fitted with an automatic take-up motion. These are manufactured in the School of Arts, Madras, which can turn out a loom with a 54-inch reed space, exclusive of reeds and healds, for Rs. 85. The latter are sometimes of country make, but the best reeds and healds have been obtained from Blackburn, England, and cost 2½ annas per 100 dents and 5 annas for the corresponding number of eyes. The reeds are made of brass and the healds are fitted with steel eyes. Mr. Chatterton points out that in the loom described above cloths can be manufactured from yarn of coarse counts or a degree of fineness beyond that for which there is any considerable demand. The bulk of the work turned out by these machines is with yarn ranging from 60's to 100's; but, to demonstrate the practicability of weaving them, much finer cloths than these have been manufactured, and it is understood that in the hands of a skilled weaver this loom can be used for any class of work that can be done on the native hand-loom.

For the present, attention in the Madras Presidency is mainly directed to improvements in the methods of preparing warps and sizing them. Experiments in hand-sizing have proved a failure, and it seems almost certain that the present methods of sizing will have to be retained in any process of warping which may be devised. Already the use of warping mills is very common throughout the Madras Presidency, and in Salem, for instance, it is usual for weavers to get their yarn warped at a separate establishment where nothing else is done.—*Textile Mercury*.

THE SPANISH WINE TRADE.

Spain has made great sacrifices for the sake of her vineyards, and the loss of many of her forest lands, and resultant droughts may be traced to the manner in which extensive tracts of country were laid bare for the planting of vines. Doubtless at the time that the phylloxera made such ravages amongst the French vineyards and obliged France to look for her supplies south of the Pyrenees, the Spanish wine growers secured a rich return, but it was not long before the Spanisn vineyards were also attacked, and while the French growers lost little time in replanting, the Spaniards, being as a rule too poor to afford the necessary heavy expenses, were obliged to abandon their holdings. Within recent years some of the wealthier landowners have endeavoured to create special brands, in imitation of French clarets, and light, white wines, and some have already met with considerable success. Unfortunately, however, the majority of the wine-growers, possibly from necessity, have been content to adhere to their primitive methods and produce, so to speak, the raw material either for home consumption or for others to elaborate, and for which they have been obliged to accept whatever price the high protective tariffs of other countries have allowed. The United States Consul at Barcelona, reviewing the Spanish wine trade during the past year, says that prices steadily declined until the month of July, this being due in the first place to the abundant vintage of 1905 in the south-eastern part of Spain, and the excellent outlook for 1906, not only throughout Spain, but also in other wine-growing countries, such as France, Italy and

Portugal, and, in the second place, because of the termination of the commercial treaties with Germany and Switzerland. The extensive manufacture in England of wine from raisins, also in some measure affected the sale of Spanish wines in Great Britain. From August onward, the lack of rain began to injure the grapes, and prices began to recover, assisted by the commercial *modus vivendi* with Switzerland. At the same time the home demand improved, especially in the wheat-growing provinces, where the splendid crops had brought prosperity to the inhabitants. With the exception of sherry, the trade with the United States is unimportant. The recent commercial treaty may, of course, help the sale of Spanish wines in America, but leading growers and shippers do not anticipate any very great results from it. Altogether, the present condition of the wine trade in Spain is not very favourable. Many years, it is said, must elapse before the country can hope to secure a firm hold on foreign markets for her better wines, and not until the wine-growing districts of Rioja, Aragon and Valencia are able to produce the same quantities they formerly did. It is estimated that with the present rate of production, the proposed abolition of octroi dues, should it ever be carried out, would so increase the home consumption, as to leave very little common wine for export. The heavy cost of carriage by rail, enhancing as it does, by 30 to 50 per cent. the cost of the wine sent from the Valdepenas and central districts of Spain, makes it all but impossible to market these wines abroad. The shipments of common wines show a falling off more noticeable, however, in the declared value than in the actual quantity. The 1906 figures were 28,470,000 gallons, valued at £1,890,000, against 42,218,000 gallons, valued at £3,231,000 in 1905. The exports of sherry, however, increased from 406,450 gallons in 1905, to 1,003,442 gallons in 1906, valued at £126,000 and £243,000 for the two years respectively.

MEXICAN BROMELIA FIBRE.

Among the collections of fibres from tropical America shown at exhibitions has frequently appeared a long silky vegetable fibre of a greenish colour, and showing great strength, though only an expert might particularly notice the small hanks into which the fibre is made up. When a specimen is unwrapped, however, the fineness of the fibre and its extraordinary length become apparent, for six feet is a common length. So long is the fibre that it is difficult to break even a few filaments by direct strain without cutting into the hands. According to the Bureau of the American Republics, this is produced from the long narrow leaves of a "wild pine" belonging to the genus Bromelia. The nomenclature of the species is confused, however, for the fibre has been variously labelled in the museums and at exhibitions *Bromelia sylvestris*, *Bromelia pita*, *Bromelia pinguin*, *Bromelia Karatas*, and *Karatas plumeri*. Its most common names are pita, pinuella, pinguin, and silk grass, though "pita" is meaningless, and silk grass is applied to so many other fibres that the name is worthless. The better names are pinuella and karatas. In the regions of Southern Mexico, from Oaxaca to Vera Cruz, where the plant grows in great profusion, the fibre is used largely for fine woven textures, where strength and durability are essentials, such as hunting bags and other forms of pouches. It is also used for sewing threads, and was formerly employed for sewing shoes. The fibre is cleaned by hand, and the great length of the thin narrow leaf, which is armed along its edges with sharp spines, makes it a tedious operation, hence the high price of the fibre. Efforts are being made to clean the leaves of the wild pineapple by machinery, and some fair examples of the fibre have been turned out experimentally in small quantities, so that future experiments are looked forward to with interest. The difficulty in the way of machinery extraction, is largely due to the fineness, and length, of the leaf, a machine powerful enough to scrape off the hard epidermis enclosing the fibre layer being too harsh in its action, thus injuring the fibre. The production of well cleaned, unbroken fibre by machinery, and in commercial quantities, would no doubt give to manufacturers a new textile which might enter into some of the present uses of flax, while the peculiar silkiness, and the colour of the fibre, would adapt it to the manufacture of many beautiful woven articles, such as fancy bags, and even belts for summer wear. It would doubtless make superior fishing lines, and with further preparation and bleaching, it is probable that the fibre might be employed in a wide range of woven fabrics of great beauty. An Italian authority states that in Brazil and Guiana, where a similar (if not the same) plant abounds, the fine silk fibre is manufactured into many *articles de luxe*. In an old work on Mexico a species of Bromelia is referred to, which is said to yield a very fine fibre six to eight feet long, "and from its fineness and toughness, it is said to be commonly used in belt-making work. It also finds application in the manufacture of many articles, such as bagging, waggon sheets, carpets, &c., besides being a valuable material for making nets, hammocks, cordage and many other articles in common use." This undoubtedly refers to the common form of Bromelia. A species of short-leaved Bromelia grows in Paraguay and Argentina, producing a somewhat similar fibre, which is known as Caraguata, the product of *Bromelia Argentina*. The filaments from this species are rarely longer than four feet, and while the fibre is short and strong, it does not compare with the pinuella fibre from the regions of Oaxaca, Mexico. Bromelia fibre is closely allied to the famous piña, or pineapple fibre of the Phillipines, from which are manufactured beautiful textures, such as fabrics for ball dresses, and handkerchiefs of gossamer fineness. There is said to be little doubt that with a careful preparation, some of the wild pineapple fibre might be employed in the same manner.

ARTS AND CRAFTS.

Art and Advertisement.—The First Annual Business Exhibition at Olympia would not, at first sight, appear to have very much to do with Arts and Crafts. It suggests, rather, a show of systems of filing. office furniture, typewriters and fountain pens, than of anything even remotely connected with art. And all these things, naturally, form a very important portion of the exhibition, as they do in office equipment in the present day. But, there is yet another part of modern business method advertisement—which plays a very important part nowadays, and which was, fitly enough, largely represented at the show. Nearly everything is advertised more or less, and no business exhibition would have been complete which did not include methods of advertising. Certainly the one held at Olympia did not err on the side of excluding or discouraging them; and the opportunity of showing what is being done and can be done in the way of printing for advertisement, was seized not only by the large advertising agents and poster printers, but by old-established firms connected with a very different type of work, like Messrs. Bemrose and others.

The Three-Colour Process.—We are all familiar with the strides which have been made in colour printing in recent years owing to the introduction of the three-colour process. We have grown accustomed, maybe we have even come to demand, coloured illustrations in books of various sorts; and we expect such illustrations in comparatively inexpensive books to rise to a level to which some years back the most expensively produced folios would hardly have attained. At Olympia, we had an opportunity of seeing on a large scale what a change the process had effected in the way of showcards and other advertisements. Of course, chromo-lithography is still employed, but by far the larger proportion of this kind of work is now done by the three-colour process, and done in a way which is certainly more artistically attractive than what was being done say a dozen years ago. Advertisements, it goes without saying, are primarily meant to attract, and, in nine cases out of ten, neither the advertiser nor the person who looks at his showcards, or whatever they may be, cares anything about art for its own sake; but it would seem that even from a purely commercial point of view a better (more especially if it happens to be at the same time a cheaper) process is sure to win its way to the front. This particular process, at least, has certainly caused something which amounts almost to a revolution in the domain of colour printing.

Poster Design.—In the matter of posters, again, we see very clearly how very much fashion has changed of recent years. Probably most of us have been struck by the difference between the hoardings of the present day and our youthful recollections of what such places used to look like, and have wondered at times, more or less idly, how much of the improvement in their appearance was due to the designer, and how much to the bill poster—for posters are, undoubtedly, better displayed than they were even two or three years back. In the busy streets of a large city, however, there is barely time to glance at the posters, and none to study them; at Olympia, on the contrary, it has been possible really to consider them—and to see how great a change has come over their design. It is not merely that here and there a man like Hassall has grasped what a good poster should be, but that the aim of the poster designer is essentially changed. He no longer desires to cram everything he can think of as being connected with the article he is advertising into one poster—he no longer tries to see how many different colours he can get into the same bill. He has changed all that, and seeks now rather to call attention to one fact in as simple and direct a manner as possible. It is astonishing, too, to see how many of the most successful advertisements of to-day are printed mainly in black and white, with just a dash of red and yellow, whilst nearly all the most attractive posters are printed in few colours, and are practically innocent of shading. The modern poster may often enough be far from satisfactory from the point of view of art, but it is, as a rule, a businesslike and workmanlike production enough, which is in itself something for which to be grateful. Technique without art leaves much to be desired, but art without technique is surely a contradiction in terms.

Lettering.—Another direction in which there are signs of change in advertising methods is in the way of lettering. Slanting letters, shaded more or less after the manner of old-fashioned public house signs, are with us still, and to these have been added certain modern attrocities in the way of wobbling O's, wandering S's, and other letters placed at varying angles with little or no attempt to range. There is also a certain amount of imitation handwriting and typewriting which is far from beautiful. But in spite of all these things it has to all appearances dawned upon both printers and advertisers as a whole that the surest way of making advertisements effective is to print them in simple and legible type—and that it is no use puffing so-and-so's soap or someone else's cocoa in ornate letters which leave the man in the street in some doubt as to what you are trying to push—or which, failing that, take some appreciable time to decipher. Ordinary leaflets, notices, and advertisements generally are meant to call attention to themselves and to be cursorily read. For this the two great essentials are simple, legible lettering and good spacing, and it appears that in both these matters art and advertisement can really go hand-in-hand. There are, indeed, advertisements (attractive enough in one sense) in which anything approaching to art is conspicuous by its absence—but in most cases the notices and leaflets at which anyone with any pretentions to taste is inclined to look twice, are those which are printed in a refined type and spaced

and generally set out with a certain amount of artistic feeling.

It is easy enough to rail at advertisement and natural to deplore its necessity, but since it is there it is at least encouraging to see that it is not always or increasingly vulgar or even commonplace. Certainly anyone who went to the first Business Exhibition and brought away with him a fair number of the numerous leaflets, &c, which were offered him could not fail, if he took the trouble to go through them afterwards, to be impressed with the fact that their general get-up was, in the great majority of cases, a very great deal more tasteful and more pleasing than it would have been a few years ago.

The Central School of Arts and Crafts.—Londoners have again had an opportunity of seeing the results of the year's work at the Central School of Arts and Crafts. The school has now been at work for eleven years, and has a very comprehensive curriculum. The works shown, indeed, range from architectural drawings, modelling, and stained glass work, to bookbinding, book illustration, enamelling, painting on china, and miniature painting; and there is a fair-sized collection of embroidery, lace, cabinet-making, and silversmiths' work. The standard of proficiency reached in the different classes varies very considerably, probably because in some cases the students are connected with the trades they practice, whilst in others they are amateurs. The bookbinding, if not strikingly original, shows very good workmanship. The school has always been noted for its writing and illuminating, and there seems no falling off in this respect. The stained glass painting students seem to have been encouraged to copy heads from Renaissance models, with the rather odd result that, whilst four or five of them have reproduced in glass heads from pictures by Botticelli or by Venetian artists, only one has sought his inspiration in old glass and copied the celebrated head of the Constable in the Montmorency glass. The embroidery class appears to be very popular, and a good deal of executed work is shown. There is comparatively little gold thread work or very fine silk embroidery, but the coarser kinds of embroidery and work which is done, or could be done, in the hand, are well represented. One or two of the students in this class seem to have a very good sense of colour. Some of the enamel is quite ambitious, and there is some competent silversmith's work. Quite a number of museum studies were shown; some of them of the very slightest description, others more finished, and a few designs for textiles, &c. But the designs form only a very subsidiary part of the exhibition. It would seem that the school is intended at present to turn out craftsmen with a knowledge of design rather than to train designers for manufacture. It will be interesting to see when it moves into its new quarters whether this part of its work will continue to be almost exclusively developed as it is now.

GENERAL NOTES.

Electric Lighting in Spain.—The extension of electric lighting in Spain is noticeable. In his report on the district of Bilbao, just issued (Cd. 3283) Mr. Consul Maclean says that even the villages in the interior are supplied with cheap lighting and power, being favourably situated in the vicinity of the many waterfalls which abound in the north of Spain. The Bilbao Co-operative Society increased their power last year, and now utilise four motors of 1,200 horse-power, producing 800 kilowatts. Their machinery was obtained from Swiss and German firms. La Compania Electra, in order to compete with the society, have reduced their price to fourpence per unit, and have also extended their cables to the villages and towns on both sides of the river Nervion —a distance of about nine miles—thus competing with small local companies. A Franco-Spanish company has been formed at Irun, on the frontier, for the purpose of putting up a water-driven electric plant to supply cheap power to the south of France.

Barcelona.—Barcelona seems to differentiate itself from most Spanish towns not only in its political views, but in municipal enterprise. In his report on the trade and commerce of the district (Cd 3283), Mr. Acting-Consul-General Smithers suggests that Barcelona has a more complete system of electric trams than any other city in Europe. German and Belgian companies control the whole of the many lines, the only British company having been sold to a Belgian syndicate last year. Various small extensions were made in the year under review. A German company carried a line through the Calle Muntaná, one of the principal arteries connecting the city with the neighbouring suburb of Bonanova, and the Belgian company owning the Sarria to Barcelona Electric Railway have extended their line about 1½ kilims. to the foot of the hills, and thence have built a funicular railway to the mountain village of Valvidrera. The entire journey from Barcelona to Valvidrera takes some 40 minutes, and it is not surprising that many villas for summer residence are being built in the village, which is about 1,200 feet above the level of the sea. The public lighting of the city is on an elaborate scale, and private lighting by electricity is very general, and daily becoming more so, with the result that there is plenty of work for electrical engineers and fitters, while dealers in apparatus are kept constantly employed. The authorities are doing their best to improve the condition of the provincial roads, and most of them can now be used. The only auto-mobile factory in Barcelona is a very small one, turning out about 30 cars per year, so that a large number of cars have to be imported. Mr. Smithers says this branch of trade has been neglected by British manufacturers, French machines being about the only ones seen on the road.

Journal of the Society of Arts.

No. 2,855. VOL. LV.

FRIDAY, AUGUST 9, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

MULREADY PRIZE.

The Council of the Society of Arts are prepared to offer, under the terms of the Mulready Trust, a Gold Medal, or a prize of £20, for competition amongst students of the Schools of Art of the United Kingdom, at the Annual National Competition to be held in 1908.

The prize is offered to the student who obtains the highest awards in the following subjects:—

(*a.*) A finished drawing of imperial size from the nude living model.

(*b.*) A set of time studies on a small scale, from the nude living model, executed in a short time, of varied shortly sustained poses (mounted on not more than two imperial size mounts).

(*c.*) A set of studies of hands and feet from the living model (mounted on not more than two imperial size mounts).

(*d.*) Drawing from the life, including memory life drawing done at the Examination in May, 1908.

No student will be eligible for the award who does not pass in the Examination (*d*) in drawing from the life, and who does not obtain an award for (*a*) the finished drawing of imperial size from the nude living model. The other two subjects are optional.

The works must have been executed between 1st April, 1907, and 31st March, 1908.

The recipient of a prize awarded under this trust in 1892, 1893, 1896, or 1903, cannot compete again.

The drawings, &c., are to be submitted, with other school works, in the usual manner to the Board of Education, South Kensington, in April, 1908. Each competing drawing must be marked "In Competition for the Mulready Prize," *in addition* to being labelled according to the Regulations of the Board of Education.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

ROMANESQUE ORNAMENT.*

BY F. HAMILTON JACKSON, R.B.A.
Vice-President of the Society of Decorative Designers.

Lecture I.—Delivered February 25, 1907.

I suppose each one of us has his special preferences in art matters, and in all probability holds that those forms which appeal to himself are those which are worthiest the attention of all, and, in fact, that he who does not appreciate them with an equal enthusiasm to his own is lacking in some quality necessary to the full rounding of his nature. This may generally be inferred at least from the opinions expressed in public by those who think themselves qualified to speak, and I am not sure that such heated advocacy is always disadvantageous, for it is astonishing how great an impact is required to force the British public to move even an inch or two towards the appreciation of any matter connected with art. To-night, however, I am happy in knowing that to such an audience as I have the honour of addressing there is no need to apply the spur. You are already interested in all forms of art, and eager to increase your knowledge of any one which is considered admirable, and will pardon the enthusiasm of one who thinks his subject, "Romanesque Ornament," one of the most beautiful styles the world has seen, joining, as it does, to great ingenuity of arrangement and beauty of line in the design a corresponding completeness and mastery in the use of the materials in which it is carried out, combined with a noble restraint and architectonic feeling which has often been lacking to the craftsman who possessed perfect mastery in the use of the tool.

Romanesque is a name given to a round-arched architecture which was developed from

* These lectures were fully illustrated by photographic lantern slides.

classic and Byzantine forms, and in which the principles of construction that subsequently burst forth into the full flower of scientific Gothic germinated and were developed. With the architecture we are only concerned in so far as it affects the production of ornament, but I should like to repeat that the principles which were the germs from which the splendour of Gothic architecture sprang are all to be found in Romanesque; and this indicates a mental calibre in the designers and master builders at least not at all inferior to the great names of a later date. As far as carved ornament goes (from which many of my examples will be taken) the style was at its best during the latter part of the twelfth century, lingering rather later in Germany and much later in Dalmatia, where the pointed arch was used very little. The finest examples are perhaps to be found in France, where the genius of the people for figure sculpture allowed of an earlier mingling of figure and ornament of equal excellence. In Italy and Germany the ornament is generally superior to the figure work, and the same remark applies to our own country.

To-night I propose to show examples which will prove the variety and beauty of the style in different countries, commencing with France. The tympanum of the south door of the church of St. Pierre, Moissac, ascribed by M. Marignan to the middle of the twelfth century, though M. Rupin dates it earlier, which has been thrown on the screen, is a good example of the sculpture and of a certain type of the ornament of the period in this part of France. Note the curious border made by the convolutions of a folded riband, a pattern which is common in painted decoration, treated rather more geometrically. The large rosettes upon the lintel, which is made of several pieces of a Pyrenean marble, indicating a different origin from the rest, are repeated on a fragment at Cahors, the damaged north door of the cathedral in this city shows even finer design in the central figure of the tympanum, though the subjects flanking it from the life of S. Stephen are out of scale. The best sculpture in France was produced between Angoulême and Cahors at this period. The cathedral at Autun has another example of a very fine tympanum, and in this case the surrounding ornament is of the same period, while at Moissac the setting is of a somewhat later date. This gains further interest from its being a nearly exact copy of that executed at Vézélay a few years earlier except for the pose of the principal figure, and from its being the earliest French instance of the sculptor signing his name. "Gislebertus me fecit" is found in the centre of the band of inscription, 1150. The subject is no longer a Majesty, but the Last Judgment, with the weighing of souls and separation of the sheep from the goats, which is frequently met with on Gothic tympana. The border of signs of the zodiac and labours of the months is simply a repetition of the corresponding portion at Vézélay. In these carvings you will observe a strong Byzantine influence in the treatment of the drapery, and a conventionality which is only beginning to yield to the study of nature, and there is little doubt that the school of Toulouse, the earliest and least accomplished of the French schools of sculpture, so far as its earlier works are concerned, found inspiration in copying Byzantine ivories. The early reliefs of apostles in the cloister at Moissac, preserved from the building of Abbot Ansquetil, destroyed in the fire of 1188, show soft modelling and deeply-cut outlines to force it up, as do the somewhat similar reliefs encrusted in the wall of the choir of S. Sernin, Toulouse, which probably formed part of the decoration of the ancient cloister there. At that time the only provinces of Gaul which had preserved any traditions of antique art were those in which the Roman municipal organisation was still maintained. Several towns of the south governed themselves *intra muros* as under the empire, and therefore retained their bodies of artisans and traditions of the art of antiquity though much dulled. Toulouse was the city which had best preserved its municipal organisation and the practice of the arts had been continuous within its walls. It became, as might be expected, the centre of a powerful school, the influence of which was widely spread. Arles and S. Gilles show its influence in the modification of the classical tradition. The pattern upon the cap to the left of the two now on the screen, from the triforium of S. Sernin, shows forms which are almost exactly reproduced in the beautiful capital to the right of the two from the cloister of Moissac.

Beneath the tympanum at Moissac which we were looking at just now is a very remarkable piece of sculpture, the central pier. It is the work of a man of genius and shows a curious mixture of influences. The pose and interweaving of the lionesses have been held to suggest a northern origin, which the method of using the tool and rendering detail contradict,

while the figures of the prophets at each side recall figures which one has seen in Italy, but with a greater feeling for grace and completeness in the rendering of form.

Here also the influence of Byzantine design is very evident, specially in the arrangement and treatment of the hair and the flow of the draperies, mixed with apparent study of nature. M. Rupin says it bears the date 1100 and the name Asquilinus. In the museum at Burgos in Spain is an Arab casket of the eleventh century from the monastery of Silos in which this detail of the crossed lions occurs among hunting scenes, stags, and animals resembling Assyrian monsters, which may be traced still further back on a Sassanian vase in the Cabinet des Medailles at Paris, and on Assyrian cylinders, and is plainly one of those Oriental features which were found so inspiring by the ornamentalists of the south of France. In the narthex (which is generally given a rather early date and has an interesting attempt to solve the problem of the junction of vaulting ribs) the caps are carved with beasts in somewhat the same manner, though of a different stone, and the lioness to the right clearly shows her near relationship to the finer animals on the pier.

It is a matter still disputed by French archæologists whether the beautiful doorways with architectonic figures attached to the columns of the jambs were an invention of the South, of the west, or of the northern part of France, some holding that the Provençal School influenced the sculptors of Chartres, though this is very doubtful, regard being had to the several dates; some that the sculptures at Le Mans were the earliest, and some that they first were used by Abbot Suger at St. Denis. Unfortunately, the door which we know that he finished in 1140 no longer exists; the dates of many of the existing examples are matters of deduction rather than proof, and the question is complicated by the probability of earlier carvings having been used up at a later date, as was certainly the case in some of the Italian buildings. Take the beautiful west portal at Chartres, for example, probably erected as a porch between 1150 and 1175. It is evident from the difference of height in the figures, from the change from time to time in the patterns of the intervening portions, and from the fact that some figures have canopies and others none, &c., that if the various parts are contemporary and all made for the same piece of work, the sculptors had so much liberty as to amount to license. You will observe that the pattern sometimes changes with each fresh piece of stone, showing that the carving was done before the stone was put in place, while sometimes the design runs through several courses unchanged; and when it is remembered that no less than three foundations for the western walls exist in different parts of the nave, showing two re-buildings, and that there was a destructive fire in 1194, after which the cathedral was entirely re-built, I am sure that you will realise that the problem of the exact date of execution of any part is a difficult one. But how beautiful it all is! The majestic figures aiding the stability of the design by the lines of their composition, while the variety of pattern, the excellence of carving and ingenious composition of line in the ornament between is beyond all praise. The tympanum of the central door is especially fine in composition, showing the usual subject on that part of the doors of the Romanesque period in the north of Europe, Christ in glory, surrounded by the symbols of the evangelists. Doorways of this type of varying degrees of excellence are to be found at Le Mans, Bourges, Étampes, and other smaller churches, and records of their previous existence in several towns where they are no longer to be seen, as well as in other countries.

In Provence, which was the favoured province of the Roman empire from B.C. 150 till about 450 A.D., and was the first of the Roman Transalpine establishments, sculpture is treated differently, the Gallo-Roman tradition being stronger and the remains of antique sculpture of more frequent occurrence; indeed, at Arles, as also at Vienne, the carving of sarcophagi continued till the close of the sixth century, if not later. It has retained the name given it—Provincia, the province. The ancient kingdom of Arles was separated from the empire of Charlemagne in 879 by the marriage of Hermengarde, daughter of Louis le Debonnaire with Bozon, Count of Ardennes. At the close of the eleventh century the marriage of the heiress of Provence united her possessions with those of the Count of Catalonia, and various portions of Northern Spain and Southern France were ruled by the same lords during a great part of the Middle Ages. The Spanish royal hero, Jaime el Conquistador, was born at Narbonne, which had been the residence of Visigothic kings, and, for forty-two years of the eighth century, of Arab Sultans. The courts of their Spanish lords were frequented by the minstrels of Provence, and from the Arabian settlers

of the Peninsula they derived the ornament of rhyme, the form of their verses, the character of their poetry, and that superior intellectual culture which for three successive centuries made their language and poetry the admiration of Christian Europe. And where this influence affected literatnre, similarly ornamental art was benefited, though this was only one of the ways by which Oriental forms entered into the repertory of the designer. The Provençals were the natural intermediaries between France and the Crusaders established in Syria, and the church of St. Trophime, Arles, the façade of which is the best-known example of Provençal sculpture, elaborately carved with figures and ornament, in its general proportions and profiles is based on the same lines as many of the churches of Syria which the Crusaders saw between Antioch and Aleppo. It must be remembered that Antioch was in Western hands from 1098 to 1268. The sculpture, however, follows the Gallo-Roman tradition in the main, though affected by Byzantine carvings which were part of the commercial products continually arriving from Constantinople, such as costly covers of books or diptychs, ornamental furniture, and the splendid textiles which were for the ornamentist a still more fruitful field of suggestion. The generally received opinion is that this façade was built late in the twelfth century, or even at the beginning of the thirteenth, as some contend, but certain irregularities in the arrangement of the figures suggest alterations, and it is precisely in those parts that the detail of costume occurs which is relied on, perhaps insecurely, for fixing the later date; the shape of the mitre of St. Trophime in the centre panel of the five. In the cloister is the mortuary inscription of a master builder, Pons Rebolli, with the date 1183, who was priest and canon regular and also operarius of the church as the inscription states, proving that work was going on shortly before that time, though the epitaph of Pons de Bascle, regular canon, gives the earlier date of 1165. The iconography of the whole is much upon the usual lines. Christ in glory, crowned as at Moissac, with the evangelistic beasts in the tympanum, half lengths of angels below and prophets and apostles on the lintel. A fresh detail is the row of the blessed led to heaven in close order on one side, an angel handing their souls to Abraham, and the damned in charge of demons walking through flames on the other, which form a frieze above the row of colonnettes.

The church at S. Gilles is a still finer example of the same style, which shows the influence of the antique to an even greater degree in the figure sculpture, and in much of the ornament, while in certain details the copying of *motifs* taken from Oriental textiles is equally apparent. This town was one of the principal ports at which the Crusaders embarked during the earlier period of those wars, and was very prosperous, with a flourishing commerce and many rich merchants. The church was commenced in 1116, and the façade is probably of 1140 as regards the main portion, the Albigensian wars and other difficulties, as at Toulouse, stopping the artistic development of the country and sapping its prosperity. It is thought by some that the design was at first arranged as at S. Trophime and that the side doors are a later addition, but the mouldings and the carved ornaments are quite similar on the archivolts and abaci of all three doors, and though the central door shows signs of change in design, those at the sides are consistent throughout.

It is curious that the most celebrated piece of Poitevin architectural sculpture, the façade of Notre Dame la Grande, Poitiers, has characteristics which are more closely connected with the art of Saintonge and Angoumois than with Poitiers itself. The conical pyramids with which the turrets at each side of the façade terminate, as does the central tower, are distinctive features of the Romanesque buildings of Saintonge, and are also found at Perigueux, and the lavish decoration of the archivolts is also not uncommon at Saintes and in the vicinity. The imagination of the sculptor has run riot over the whole surface of the façade, and a general richness of ornamental effect compensates for a certain inferiority in the style of the figure sculpture. Whether the incursions of the Northmen left behind a liking for northern savagery with a predisposition to quaintness in the treatment of animal form is a debateable point, but certainly there is a good deal of grotesquerie in the details of some of the archivolts, as in the dogs which surround this arch on the right, and the character of the ornament is very different from that of Provence. You will notice that each stone of the arch has a completed unit of design upon it, so that as the stones narrow or widen the design varies in its lines though apparently intended to be a repeating pattern. The same thing may be observed in the simpler Norman patterns, of which examples may be seen

much nearer home, as, for instance, at New Shoreham. This façade was added in the twelfth century to an eleventh century building and touches a point beyond which richness can scarcely go, and one hardly likes to think of what the original effect must have been when the stone was painted and gilded! The arcades are filled with statues of the twelve apostles with two bishops thrown in, perhaps SS. Martin and Hilary, and below the string course the spandrils are also decorated with carving, the subjects being Adam and Eve, Nebuchadnezzar, a group of prophets with scrolls, Moses, Jeremiah, Isaiah and Daniel, the Annunciation, Jesse with the tree commencing to grow from him, the Visitation, the Nativity, &c. The little arches below the string are all filled with carvings, and elaborate patterns decorate the arch mouldings, while the ground of the gable, in the centre of which Christ stands in glory within a mandorla is patterned by the shapes of the facing stones of which it is constructed.

The Church of S. John Montierneuf (a corruption of *monasterium novum*) shows in the poor remains of its central tower the same kind of design as Notre Dame la Grande, which was probably due to the same architect, a monk named Pons. It was founded in 1075, and consecrated by Urban II. in 1096, on his way from Clermont, where he had been preaching a crusade. It still retains a wall arcade round the apse of the original building. Here you see a less-developed form of the intertwining stems and leaves characteristic of the later Romanesque, and I have selected a grotesque also from the caps of this arcade, which shows a mode of avoiding the awkwardness of two animals' bodies meeting at the angle, where the volute would naturally be, having only one head between them. The founder of the monastery, Count Guillaume Guy-Geoffroy, used to visit the monks every day when he was at Poitiers, and after his death they still set his place at each meal to keep his memory green. The tower of S. Porchaire is of 1068, and shows in its walling a reminiscence of the Roman *opus reticulatum*, which may be held to connect it with the external inlays of Auvergne, though there is no variation of colour. The church is an instance of the reputation of the saint who was buried within it, replacing the original dedication as at S. Hilaire and S. Radegonde, both of which churches originally bore different names. The caps at the door of entrance are carved with quaint devices of an Oriental derivation—a common symbolic subject is Daniel in the lion's den, typifying the Christian amid the temptations and troubles of the world. Here we have the lions without Daniel, but with a central tree upon one, perhaps typifying the abbatial jurisdiction, exercised "inter leones," and two birds drinking from a vase on the other. The Church of S. Hilaire is an exceedingly interesting building, though it has suffered so much from restoration that it is difficult to make sure of the age of the different parts which have been smartened up. It has been many times burnt, and a drawing in the public library, made in 1804, shows that the nave vaults were all down then. It has curious octagonal domes over the nave like those at Le Puy, which may have been copied from that cathedral, since we know that the monks rescued the relics of S. Hilary from the flames of one of the Norman incursions in the ninth century and took them to Le Puy. The carving of the caps appears to be of the eleventh century and belongs to the church re-built and enlarged by the Burgundian Countess Agnes in the middle of that century. Among much rough stone-cutting some finely designed subjects occur. The Burgundians have always been good carvers, the character of the native limestone assisting their development, and it is possible that the Countess may have imported some sculptors to assist in the decoration of her new church. Socrates tells us (lib. 7, cap. 30) that the Burgundians, in his day, were workers in wood, and so gained their living, and in the crypt of S. Benigne, Dijon, is a very curious cap which was built into the eleventh century wall, and is therefore considered to be earlier, which bears monsters and interlacings on its sides resembling Scandinavian work.

At Le Puy, which is a Gallo-Roman town, is an early cloister which Viollet-le-Duc held to be the earliest in France. It has, unfortunately, been thoroughly restored, as has the whole cathedral, with considerable alterations, but a good deal of fine ornament may still be seen. The oldest portion of the cloister appears to belong to the eleventh century, the rest to the twelfth. The walk adjacent to the cathedral was entirely rebuilt when the restoration took place between 1850-57, but the other sides were only repaired. The south-east porch is a fine and original conception, probably built at the end of the twelfth century, and showing an entirely different type of ornament to that at Poitiers, very much more

closely derived from antique forms, but with a suggestion of Arab influence in certain details. and in the shape of the bounding lines of the caps. Observe, too, the curious colonnette to the left, which reminds one of our Saxon turned baluster shafts. A triangular tympanum crowns a door beneath the porch, and bears an inscription of the fifth century, and the pattern of opposed S's—perhaps an ancient symbol suggesting fecundity—which surrounds the arch was also found on some fragments belonging to an earlier church which were excavated on the site. Cattaneo figures a fragment with a similar pattern from S. Maria in Valle, Cividale, among the work of the eighth and ninth centuries, in which that chapel is so rich. This pattern of cap from the cloister shows Burgundian influence, while the lava inlays on the wall surface may possibly have been imitated from the marquetry of wood and ivory of some imported Eastern furniture, or perhaps a development of the Roman *opus reticulatum* in colour. Another type of capital is a rough copy of a sixth century motif which occurs in several places in Italy, but of which a variant in the Cathedral of Parenzo is so near that a comparison of the two suggests a struggle on the part of the sculptor to render in an intractable material the ornament which the marble allowed to be carved with some approach to perfection. Here is another example of figure work upon the further cap. The cutting of the stone is quite adequate, though the figures terminate with the knees, and the nearest cap shows fully developed patterns resembling these we have seen at Moissac and Toulouse. In the cathedral itself are some exceedingly fine capitals, unfortunately, as at Autun, at too great a height for satisfactory photography, but these twin columns from the south transept show characteristic ornament, with the same division into two stages as occurs in the cloister and a running pattern of conventional foliage in the lower, while in the further one well-carved heads of men and animals take the place of the usual flower. The bands surrounding the stems betray a metal original for the ornament. From the Rocher Corneille, which is crowned by the colossal statue of the Virgin which you saw in the general view of the cloister, an excellent idea of the arrangement of the cathedral and its surrounding buildings may be obtained. The little cloister is sunken between the building with the twelfth century chimney (to which a fireplace belongs within) and the Hotel Dieu, to which battlements were added at a later date. The ornamental inlays of lava, and the cupola at the crossing, which are such prominent features of the churches of Auvergne, are well seen.

On an isolated rock to the north-west of the cathedral stands the little chapel of S. Michel d'Aiguilhe, looking almost as if it had come out of a mediæval picture. There was an oratory here in the tenth century, but most of the work dates from a couple of centuries later. It has a very fine doorway, unfortunately a good deal restored, which may be taken as typical of the twelfth century carving of this part of the country. Its decoration combines rough inlaid pattern, the architectural arrangement of the carving, some figure work, and much excellent ornament with a decided Oriental feeling about it. A spandril at Ani, in Armenia, shows almost exactly the same forms as the scrolls in the spandrils of the trefoiled arch. The interior has been very little meddled with beyond an endeavour to clean the whitewash from the walls, when three series of decorations were found one above the other. It has a good many interesting caps, which show what some of those in the cloister were like before they were recut, while others which appear to be only commenced recall examples in Italy, one side of which is roughed out like these, while on the other detail has been carried further, in evident imitation of the antique acanthus foliage, of which one in the crypt of St. Miniato, Florence, may be instanced. I should like to call your attention to the very beautiful cap, with the Byzantine motif of the plant springing from the vase and with similar foliage on the abacus, which seems to me a very graceful treatment. A rather late doorway at St. Lazare, Avalon, may be taken as an example of the great richness which French Romanesque so often shows. The archivolts are covered with ornament upon every member, and the jambs have a series of columns with carving between which stand upon a very high base also richly carved with ornament and subjects. The shafts, which now are plain, almost certainly had figures affixed to them, as at Chartres, one of which has been found in the belfry, where it was used as the mullion of a window. The curious carving of chain mail upon a twisting shaft shows that even at this time the craftsman sometimes selected unsuitable ornament, but the whole effect must have been exceedingly splendid when the façade possessed its three

portals, one of which has been entirely rebuilt, while the central door has been much altered. Observe the reappearance of the folded riband pattern seen at Moissac, and a sensation of clasical forms.

It seems difficult to surpass these French examples in richness, but the next slide, from the catheral of Traù, in Dalmatia, shows that it is not impossible. This is a rather late example, and shows traces of Gothic and even early Renaissance detail, but it is Romanesque in its general arrangement. It was carved by a Slav sculptor named Raduanus, in 1240, with extraordinary mastery over the material in all the ornamental portions, though the large figures of Adam and Eve show the usual failure in the treatment of the figure. On the smaller scale of those among the arabesques, however, they may pass muster without attracting attention by their inadequacy, and the lions are decorative, though not much like the living animal. They stand on brackets, and a similar arrangement is met with in Bari and some other of the Apulian towns. The turbans upon some of the caryatid figures, one of which has an expressive face, show contact with Turks or other Orientals, a feature which again occurs in the towns on the other side of the Adriatic.

Not far from Traù is Spalato, the city which occupies the palace of Diocletian, and here a very talented carver named Guvina worked in the early part of the thirteenth century, making the doors of the cathedral in 1214, and probably also the very original choir stalls. The running pattern which divides the panels of the doors has all the characteristics of the earlier Romanesque ornament of Italy and Germany, beasts and birds occupy the scrolls, hunters pursue animals through them, and curious half figures emerge from the leaf terminations. The figure work is less inadequate than usual, perhaps owing to the later date, but certain Byzantine details betray a probable copying of ivories. The stalls show a great mixture of styles in the details, an Eastern influence in the open work which resembles the Cairene musharabiyehs, a Lombard influence in the rows of arcading, while the scroll work is Romanesque, the figures looking rather later, and the interlaced patterns appear to be a survival of those which were common in the ninth century. The camel in the square panel just above the seat shows that he, like Raduanus at Traù, had had direct contact with the East. There was a school of architectural carvers here who worked up and down the coast. The pulpit in the cathedral, a very beautiful piece of design and carving, has its almost exact counterpart at Traù, somewhat simplified. Here, as you see, we have a rather rich arcading surrounding a hexagonal pulpit with carved cornice and string, the spandrils of the arches below also having a delicate flat ornament. It is supported on six octagonal colonnettes having elaborately carved caps with long necked monsters twisting and writhing among the foliage. The caps at Traù are carved with something the same kind of design but with a suspicion of Oriental feeling in the foliage, which suggests metal, while the caps at Spalato suggest wood as the material in which the artist conceived his work. In Apulia there are several caps existing, fragments of destroyed ciboria for the most part, which have a good deal of the same character as these. The pulpit at Traù is octagonal with an arcade of two arches on each face and much less carving, the columns upon which it is supported are of precious marbles and circular in section, and the patina of age which harmonizes all the details suggests to the mind a recollection of that most harmonious of all buildings, S. Mark's, Venice. Here is also a ciborium of a pattern which is considered to have been evolved by the Roman marble workers (though the example earliest in date appears to be that in the church of S. Nicola, Bari), since there are quite a number in and around Rome. The proportions of this example more nearly approach that at Bari, and it is probable that it is founded upon it rather than upon the Roman ciboria, but the type is found again as far away as Cattaro, in the church of S. Trifone, but with loftier proportions and with more carving which rather damages the effect. These are both of them comparatively late examples and show how the style lingered in Dalmatia.

Instances have been given in which Oriental costumes and details prove contact between the East and the West, but Oriental influence was felt at a very early period. In France especially it can be recognized before the Christian era, Egyptian and Egypto-Greek objects finding their way by the usual trade routes even as far as the Low Countries, probably from Alexandria. After the arrival of the Goths Syrian influence becomes more evident. The Museum at Arles proves an active centre there for Sarcophagi copied from Roman works, but by its side another was formed in close relation with Ravenna and the

East. Examples both at Arles and Toulouse prove their co-existence till the end of the sixth century. Numerous Syrians were in France from the earliest times of the empire and the first Gallo-Roman churches were probably founded by Oriental emigrants, a mixed population among whom Jews and Greeks with the Syrians were in the majority. The "Vita Hilarii" mentions Jews at Worms, Cologne, Metz and Poitiers, and there were many at Arles. Other MSS. prove that the Syrians were everywhere and possessed of a good deal of power. Gregory of Tours shows them to us very rich and possessing objects of art. Inscriptions show the early presence of Greeks at Lyons, Bésançon, Trèves, Vienne, Narbonne, and Arles, and Councils also prove their presence in Gaul. Relics of Oriental saints were brought Westward in reliquaries which gave the suggestion of such ornament as appears at St. Jean, Poitiers. As for the Syrians, in the sixth century the most active of the Christian races, St. Jerome says that in his time they were everywhere, and that trade was in their hands. Many of them were of the labouring classes; they were gardeners, and through their means the West gained several of its fruit trees; were artisans, mosaicists, and sculptors; they exported industrial objects, such as glass, silk, leather, &c. Contemporary authors show these Syrians to us in all the maritime towns. At Orleans they formed a powerful colony, and at Paris one of them named Eusebius, in 591, bought the Episcopate by profuse presents, and soon gave to his countrymen the administration of the bishopric. It was by means of the Syrian colonies that the ideas and legends of the East were spread in the Middle Ages, and M. Courajod used to say that it was impossible to exaggerate their importance in the development of design. The biography of St. Columba, by Jonas, monk of Bobbio, shows an affinity of doctrine, of sympathies and beliefs, between the Syrians and the Irish and Anglo-Saxons, which is evident also in their art.

The principal French towns for the exchange of the merchandise of the Levant and Constantinople were Marseilles, Narbonne, and Arles, as in Roman times. The maritime towns of Provence and Languedoc had in the twelfth century, both in the kingdom of Jerusalem and at Constantinople, commercial establishments, and mooring places on the quays. Provençals had a church and a quarter at S. Jean d'Acre, while the Narbonnais traded specially with Egypt. The principal Italian commercial towns also had their quarters similarly. Among the ivories imported from Alexandria are the six which decorate the side panels of the pulpit at Aachen, given by Henry II. Dr. Strzygowski has proved that these have the characteristics of the Coptic form of Syro-Greek art; and the chair of Maximian, at Ravenna, an earlier and finer example of ivory carving, has also a very decided Syrian character, though whether it was carved at Antioch, as he thinks, or in Alexandria or Constantinople, appears doubtful. The textiles with hunting scenes in medallions, or beasts, birds, or monsters face to face, of which fragments remain here and there in Western Europe, as at Aachen, Chinon, Toulouse, Sens, Le Mans, and Durham, as well as in museums, are either Byzantine copies of motifs of Sassanian origin or Sassanian originals, and an example has been discovered in Japan quite plainly based upon these patterns, which shows that their influence spread eastwards as well as westwards. The patterns carved on Eastern ivory caskets or oliphants, in which relics were sometimes brought to Western Europe, with a similar motif also had their effect, such as the Soltikoff horn, a work of the eleventh century, which, if not carved in the East, was copied from an Oriental ivory, the similar horns in the museums of Toulouse and Le Puy, &c. In these ivories the suggestion of Romanesque subject and pattern is unmistakeable.

The pillars of S. Saba, in the Piazzetta, Venice, were brought from S. Jean d'Acre, as the sequel to disputes with the Genoese, they having formed the gate to the castle opposite the church of S. Saba. The patterns upon the sides are very characteristic, vine leaves and bunches of grapes issuing from a vase and controlled to a strict conventionalism in their growth and the spaces which they fill. Upon the upper edge of the pier is a fret with slanting sides, a peculiarity which is found in Celtic interwoven patterns. In this sarcophagus from San Lorenzo, Milan, you may see absolutely the same conventions in the central panel, and they occur also at Ravenna, Ancona, and elsewhere upon the slabs of ambos and chancel enclosures. The archivolt of the Foscherari Monument, in the Piazza S. Domenico, Bologna, made of a portion of an eighth or ninth century ciborium, and much resembling the baptistery at Cividale, has a running pattern derived from Syria, which frequently occurs, with a varying number of leaflets, supporting the ball in the centre. At Castel

S. Elia, near Nepi, is a slab with this Syrian pattern having five leaflets. It occurs at Ravenna, in fragments in the museum, and may be seen as a pierced ornament on the bronze horse-trappings from the tomb of a Gaulish warrior in the British Museum. The ivory covers of a book in the Treasury at Monza have, on one of them, a pattern in which the leaf forms are more defined, two filling the circle, as on the tomb of Theodata at Pavia,

FIG. 1.

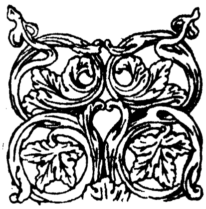

FIG. 2.

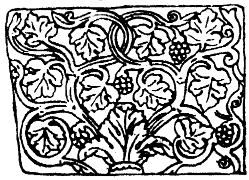
IVORY FROM THE CATHEDRAL, TOURNAI.

with a creature within, whilst the other has a beautiful pierced repeating pattern, recalling carvings of the ninth century at Como, Milan, and Rome. In the Treasury there is also a comb of ivory, ornamented with filagree and jewels. A comb of a similar shape but without the enrichments was found in 1771 on Barham Down, near Canterbury. The one at Monza is said to have belonged to the Lombard Queen Theodelinda. In the Museum at Cairo is a fragment of ivory carving, in which the vine appears springing from a vase in true Byzantine fashion with birds about the branches, which Dr. Strzygowski considers to be Syrian. The arrangement of this is a good deal like the outside of the Ormside cup of which I shall show you a drawing in connection with the Anglian crosses. Leaves of somewhat the same kind occur on the panel carved so well in the tenth century by Tutilo at S. Gall, in which he closely imitated the character of the older Italian work, to which he added the subjects of the Assumption of the Virgin and the legend of S. Gall; and an ivory in the Cathedral of Tournai has leaves and stems arranged in much the same manner (Figs. 1 and 2). A sarcophagus found in the cemetery of S. Saturnin, Bordeaux, dating from the sixth century, shows something of the same treatment, though rather freer in the underlying lines (Fig. 3); and, no doubt, in all these cases a traditional mode of filling a panel with vine leaves and fruit was followed. A version of this treatment of the leaf may be seen in another piece of sixth century work, a capital in the Cathedral Parenzo, imported from Constantinople. Mr. Butler says that in the Haurân the grape vine is the most common motif in the pre-Roman and classic carvings, and that in Christian carvings of the North of Syria it is almost the only motif used, but with a tendency to a severe conventionality; and that if animal forms were introduced, they were subjected to an equally severe symmetrical conventional arrangement.

Recent researches by Dr. Strzygowski also seem to prove a direct influence of Syrian art upon the West. In an early Evangeliar which he studied at Etchmiadzin, in Armenia, he found some Syrian miniatures of the sixth century inserted, which he holds to prove that it was customary to export miniatures from Syria. Charlemagne, shortly before his death, had a recension of the Gospels made, with the help of both Greeks and Syrians. This may explain the curious pavilions in the Godescalc and Soissons MSS., which are unlike any Western architecture, but much resemble one of the Syrian miniatures, as well as the arcading beneath which the Eusebian canons are set, which are equally similar, and of which the sixth century Syrian MS. of Rabula shows another example, with horseshoe arches. The resemblances between the school of Egbert of Trèves and Syro-Egyptian art may be traced back to the same source or may be the result of importations from Alexandria.

FIG. 3.



PANEL FROM SARCOPHAGUS, BORDEAUX.

The fine ivory in the Louvre, showing Constantine as the hero of the faith, or Justinian, which Dr. Strzygowski believes to be Alexandrian, like the reliefs on the ambo at Aachen, belonged to a Rhenish church in the middle of the seventh century, probably to Trèves Cathedral. On its back it has 350 names of believers, arranged in six columns, many of which belong to the Rhine and the diocese, names of archbishops between the fourth and

the seventh centuries, and of others sprung from Trèves. At the end of the fifth column names of Kings of Austrasia occur, from the second half of the sixth to the middle of the seventh century—Heldebert, Theudebert, Theuderic, Clothair, Sygisbert, Childebert, Athanagild, Fachileuva, Inganda. At Wolfsheim, near Mainz, in 1869 or 1870, a jewel was found which had probably formed part of a girdle. It was encrusted with jacinths and garnets, or red glass, and had upon it the name Artaxerxes in Pehlevi, the form of the letters making it probable that the first of that name was the person referred to. The discovery was of great interest as showing that the particular form of decoration of jewellery was practised in Persia in the third century, and also that there was direct communication between that country and Germany during the early Middle Ages.

In England we know the Romanesque as the Norman style, and the architectural ornament has not in general the variety and fancy which characterise the Continental Romanesque. Bishop Stubbs says the Norman brought little in comparison with what he destroyed, and little that he brought was his own! Late examples are sometimes florid, as the fine door at Kilpeck, Herefordshire, the prior's door at Ely, and the door at Barfreston, near Canterbury. Decoration was generally focussed round the doorway, which frequently had four or five recessed orders, with shafts and carved members between. Examples may be seen at Lincoln, where the house of Aaron, the Jew, has the door beneath the projection of fireplace and chimney on the first floor; also a fine doorway may be seen in the cathedral; at Iffley, Durham, Malmesbury, St. Peter's, Northampton, Kenilworth, the College Gateway, Bristol, St. Margaret's at Cliffe, and many other churches; and other ornamental features at Romsey, Tewkesbury, Glastonbury, Exeter, Norwich, Worcester, Gloucester, Castle Rising, Rochester, S. Cross Winchester, the Galilee at Durham, &c. Prior Ernulf used interlacing arcades as a wall decoration on the outside of the cathedral, Canterbury, about 1110, and repeated them at Rochester a few years later when he became bishop. Here also the mutilated figures of Henry I. and Queen Maud or Edith show that the portals of Chartres and S. Denis had their influence in the South of England, but for the most part the figure sculpture is barbarous, though the monsters and animals show a quaint fancy; and the ornament is confined to the repetition of a few forms, of which the chequer, the billet, the zigzag, single or double, and an allied form like heraldic engrailing, the nailhead, chip carving patterns, the besant, beak-heads, and interlaced arches occur most frequently. The patterns from Behioh and Safa, in Syria (Figs. 4 and 5), show that some of these forms occur in sixth century Syrian work, and scrolls like those of the church at Behioh, with winged cherubs of an Oriental type occur on the Shrine of S. Mummolus at St. Benoit-sur-Loire (678-85). Capitals are sometimes scalloped or gadrooned when on circular piers, and a kind of cushion cap like a ball with slices cut off perpendicularly is common; these freqently had ornament painted on them. The carved caps often suggest initials of MSS. with animal forms, the

FIG. 4.

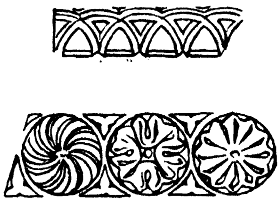


FIG. 5.

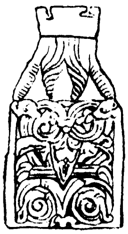
SYRIAN PATTERNS FROM BEHIOH AND SAFA.

interlacings treated flatly with scales and pearlings. On smaller objects, however, we often find beautiful and elaborate work. Examples of chessmen in the British Museum and at Oxford in the Ashmolean show considerable vigour of conception and carefully arranged ornament, as on the backs and sides of the chairs in the chessmen in the British Museum (Fig. 6). Here, too, is a very fine example of an eleventh century Tau cross of ivory belonging to a bishop's crozier which is both finer in design and workmanship than the one in the Musée Cluny found in the tomb of Abbot Morard at S. Germain des Prés and dating from the same period (Fig. 7). An earlier one is in the museum at Rouen which came from the abbey at Fécamp (Fig. 8). The drawings will show that the date of ninth or tenth century which has been suggested for this work is too early.

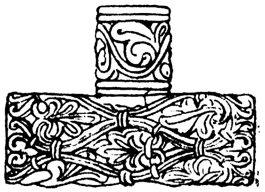
Some of the twenty-five lead fonts scattered up and down the country, most of them in the south, are Norman in design, as are a good many of those worked in stone, of which two very fine examples in Norfolk may be mentioned, at Toftrees and Shernborne, but those which are perhaps most typically Romanesque in appearance, such as those at Lincoln and Winchester cathedrals, which, as well as that at S. Nicholas, Brighton, are decorated with subjects from the life of S. Nicholas on some of the faces, and with roundels containing birds and monsters on the others, and made of black marble, were imported from Tournai ready carved, and are not English at all. There are seven in England, six in France, and three in Belgium itself. There are sepulchral slabs of the same material and workmanship at Bridlington and Ely. A very fine font, carved with different patterns on each of the four sides, and signed by the sculptor Robert of Durham, still exists at Bridekirk.

Fig. 6.



Back of Chessman, British Museum.

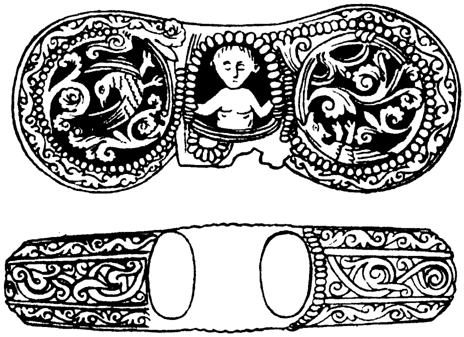
Fig. 7.



Tau from Tomb of Abbot Morard, Musée Cluny.

At Durham, the sanctuary-ring still hangs from the door, though the monster has lost his eyes of crystal. It is so much like a door-ring at Le Puy that it has been ascribed to the same smith, which seems improbable. The MSS. do not show any great advance upon those executed before the Conquest either in ornament or in figure work. The zigzag is a very ancient pattern; the earliest instances of its occurrence being prehistoric. It is found on vases from the tombs of Cnossos, on archaic pottery from Camiros, and on an Etruscan ossuary from Vetulonia of the second or third century B.C. On a piece of prehistoric pottery found in a tomb with a flint arrowhead, impressions of the arrowhead were so arranged as to produce a zigzag, tempting one to suggest this origin for the ornament. Its earliest use as architectural ornament is, I believe, on the modillions above a door at Spalato. Other of the characteristic ornaments have an Eastern derivation, such as the rosettes and besants, others from ease of production, as the nailhead and dentil, while the beakheads are probably Scandinavian, though they have a barbaric appearance which reminds one of Polynesia and New Zealand. In Sicily the Norman influence in ornament shows very little. At Cefalù there is an interlaced chevroned arcading on the façade. At Girgenti the door of the ruined church of S. Giorgio and the great window of the fourteenth century campanile (both with pointed arches) have the familiar zigzag, and at Bivona the same details occur, while the door of Santo Carcere, Catania, which belonged to the ancient cathedral, has round arches with columns in the recessed jambs and some carving of the twelfth century. Mr. Phené Spiers has informed me that two doors of one of the Cairene mosques bear decoration of

Fig. 8.



Early Tau from the Museum, Rouen.

Sicilian origin, one having the Norman zigzag and the other the cushion voussoir, which appears to be a Sicilian invention, though it is found in the church of the Holy Sepulchre, built by the Crusaders after the taking of Jerusalem in 1100. The usage of cushion voussoirs was carried back to France, and they occur in the abbey church of Évron (1150-75), the central window of the apse of Marolles-en-Brie, the doors of the churches of Chivy, and S. Pierre at Soissons, of Bellegarde, Plassac and Marignac, in the chapel of S. Gilles at Pons, and the tower of La Croix, Aisne. The strangest use of the zigzag with which I am acquainted is on two caps in S. Mark's, Venice, which are surrounded with the ornament on a large scale with a very odd effect, and the occurrence of two precisely similar in the mosque at Kairouan suggests that they are importations from the East.

In Scandinavia an exceedingly elaborate

ornamentation was developed at a rather late date, based upon the Romanesque intertwining scrolls, which was applied principally to the decoration of the doors of churches, as in the instance from Hallingdal, although also applied in a modified form to furniture and to caskets. The caskets are sometimes of bone and sometimes of wood; the rest of the work is executed in wood, often enriched with colour. Heathen symbols and incidents occur mixed with Christian, but it is pretty well established that most of the work is as late as the thirteenth century, though the Norsemen became Christians in the eleventh. From the ninth century onward they habitually robbed Western lands, and carried costly objects home with them. It appears, therefore, that these patterns are imitations or developments from Irish jewellery, &c., though some influence from the Continent is possible. Discoveries of Oriental coins in the North prove that exchange between Scandinavia and the East began after the fall of the Sassanian power, but relations became closer in the ninth and tenth centuries, to which periods thousands of Cufic coins which have been found belong.

The Gothic and later Romanesque architecture of Spain is largely influenced from France. The cloister, Tarragona, for instance, resembles that of Fontfroide, but this is not the case with the churches of the ninth century, though the South of France and Spain were ruled by the same Visigothic kings at an early date. Leovigild, who began to reign in 572, united Gallia Narbonensis to the Iberian Peninsula, and extended his rule to the Straits of Gibraltar. Recared, his successor, established his Court at Toledo. A king of Leon, Froila II. (923-4), founded an "obit" at S. Martial, Limoges, and in the obituary of the convent mention is made of two nuns, sisters of the "king of Spain" (whatever that may mean), Vrraca and Aibelis. Moorish spoils were brought to France by the Counts of Toulouse at a later date, such as the ivory casket dated by the inscription 969-70 in the Victoria and Albert Museum, with arabesques and animals intermixed filling the ground behind the medallion made by the interlacing bands, within which two men conduct a shrine or howdah placed upon the back of a camel; carved with great precision, and so developed in style that without the inscription one would be inclined to date it much later.

At the church of S. Salvador, Val de Dios, principally an erection of the ninth century, is a beautiful pierced window slab, which I shall show you in connection with somewhat similar piercings. It also has several caps with flat arabesque scrolls filling divisions planned in the same manner as these Byzantine caps at Parenzo. S. Maria de Naranco and S. Miguel de Lino, near Oviedo, were built by Ramiro 1st (842-50). The first was originally part of a palace, and has two vaulted storeys, but has been used as a church at least since 905. The other has a dome at the crossing. The decoration includes the representation of hanging shields and plaques, evident copies of metal work in stone, and details of carving which occur in Coptic monuments. S. Cristina de Lena, another early church, has patterns which are quite Comacine in character. In the caps of all there is a Byzantine feeling, and in S. Miguel de Lino is a pierced window slab which is quite Saracenic in the geometrical patterns.

M. Enlart says that Comacine influence is evident in the south-east and south of France from Dauphiné to Catalonia, and Street cites a Spanish document of 1175 in which Raymundus Lambardus with four others (lambardos) agreed for certain works at Urgel; but the Clunists were the great builders in Spain at this period.

At Santiago de Compostella is a golden cross given by Alfonso III. (874) with precious stones and filigree and a large circle at the crossing, to which a cross of the seventeenth century has been applied. A cloisonné enamel is at the back with white doves pecking a bluish fruit on a green ground bordered with pearls and golden balls with a filigree fillet between, and the arms bear oval medallions set with stones. The ciborium of Alpais in the Louvre has an inscription round the middle which is a reproduction of the device of the Kings of Granada, while on the foot is a scroll with men and dragons running through it reminding one of Toulouse caps and of ivory carvings which resemble them in design like this one from the Victoria and Albert Museum, and the knop suggests that of the Essen candlestick.

In the archiepiscopal museum at Vich is a highly interesting series of Romanesque paintings on panel which show that at that early period there was a demand for art work in Spain, and the curious tenth century MS. of the Apocalypse at Gerona indicates that the forms of Arab ornament and architecture were being assimilated by the Romanesque designers, as is shown in the carving at Toulouse and the country round of two hundred years later.

FUTURE SUPPLY OF IRON ORES.*

An examination of the field evidence supports the conclusions of de Launay and Bäckström as to the ore being a bedded deposit overlying a lava flow, but enlarged by secondary deposition. There is only too good reason to fear that the chief iron ores are comparatively limited in depth; for most of them have been formed by water containing oxygen and carbonic acid in solution, which has percolated downward from the surface. Ores thus formed are therefore restricted to the comparatively limited depths to which water can carry down these gases. On the theory, however, that these ores are primary segregations from deep-seated igneous rocks there need be no limit to their depth. They would rather tend to increase in size downward, while maintaining, or even improving, in the richness of their metallic contents. For these bodies may be regarded as fragments of the metallic barysphere which have broken away from it and revolve round it like satellites floating in the rocky crust. On this conception these ore bodies would be of as great interest to the student of the earth's structure as their existence would be reassuring to the ironmaster, haunted as he is by constant predictions of an iron famine at no distant date. It is no doubt true that many of the richest, most accessible, most cheaply mined, and most easily smelted iron ores have been exhausted. The black-band ironstone and the clay iron ores of the coalfields, which gave the British iron industry its early supremacy, now yield but a small proportion of the ores smelted in our furnaces. The Mesozoic beds of the English Midlands and of Yorkshire still supply large quantities of ore. Nevertheless, the British iron industry is becoming increasingly dependent on foreign ores. So it would be pleasant to find that the Scandinavian iron mines are not subject to the usual limits in depth. I fear the typical iron deposits of Middle Sweden and of Gellivara will follow the general rule; but Kiruna may be an exception, and its ores may continue far downward along the surface of its sheet of porphyrite. The uncertainty in this case lies in the extent of the subsequent enrichment and enlargement of the bed; if most of the ore is due to secondary deposition, then it may be restricted to the comparatively shallow depths at which this process can act; and though that limit will be of no practical effect for a century or more to come, the ore deposit may be shallow as compared with gold mines.

The geological evidence may convince us that all the economically important ores are limited to shallower depths than lodes of gold, copper, and tin; but this conclusion shall not enrol me among the pessimists as to the future of the iron supply. Twenty years ago a paper on the gold supplies of the world was read to the Association at the request of the Section of Economics. About the time that the report was issued there were sixty-eight mining companies, with a nominal capital of £73,000,000, at work upon the Rand. Nevertheless, the author, accepting the view that "the future of South African gold mining depends upon quartz veins," concluded:—"There is as yet no evidence that the yield will be sufficient in amount to materially influence the world's production. As regards India, the prospect is still less hopeful."

That quotation may be excused, as it is not only a warning of the danger of negative predictions, but of the unfortunate consequences that happen when geologists are unduly influenced in geological questions by the opinions of those who are not geologists. In economic geology, as in theoretical geology, we should have greater confidence in the value of geological evidence. Negative predictions are especially rash in regard to iron, it being the most abundant and widely distributed of all the metals. The geologist who knows the amount of iron in most basic rocks finds it difficult to realise the possibility of an iron famine; he can hardly picture to himself some future ironmaster complaining of "iron, iron everywhere, and not a ton to smelt." There are reserves of low grade and refractory materials which the fastidious ironmaster cannot now use, since competition restricts him to ores of exceptional richness and purity. When the latter fail, an unlimited quantity could be made available by concentration processes. The vast quantities of iron ores suitable for present methods of smelting in Australia, Africa, and India show that the practical question is that of supplies to existing iron-working localities, and not of the universal failure of iron ores.

* Extract from the address of Prof. J. W. Gregory, D Sc., F.R.S., President of the Geological Section of the British Association, at Leicester.

RUSSIAN COTTAGE INDUSTRIES.

The conditions governing the politico-economic life of Russia during the last two or three years have influenced manufacturing industries unfavourably; the output of several branches has been materially reduced, and that of others has ceased entirely. The same fate has overtaken the cottage industry, a type that plays a prominent *rôle* in the economic life of many districts of the Empire. This is confirmed by the reports of those zemstvos in whose governments this form of industry predominates. Thus, in the government of Moscow, the unemployed tailors of the districts of Vereisk and Bogorodsk have taken to lumbering, and the gold leaf beaters of Dmitrovsk to picking stones off village fields. According to the American Consul at Riga, the following crafts have suffered most from the hard times:—The manufacturers of brushes, the workers in brass fittings for harness, joiners, carriage makers, the weaving industry, tailors gold beating, &c. As a type of one of the industrial villages, that of Pavlovo may be taken, of which the following is a description:—This village is situated on the left bank of the river Oka, in the government of Nijni Novgorod, and has a population of 12,000. The chief employment of the village is the production of articles of metal, th

manufacture of locks alone giving employment to 1,400 cottages, with 1,500 male artificers. The form most produced is that of padlocks. Latterly the manufacture of box and door locks has been taken in hand, since the opening of an industrial school with modern workshops. Besides locks the following steel wares are manufactured—knives, forks, scissors of all kinds, razors, surgical instruments, beams for scales, corkscrews, shovels, &c., and small castings of tin and lead. In the manufacture of padlocks the prevailing type of industry is that of the family, for with the exception of the bows and springs, all the parts are made by the artificer and the members of his family of ten years old and upwards, the employment of outside help being the exception. According to size and kind of lock, a family is able to manufacture weekly ten to one hundred and fifty locks. Excluding the products of the larger factories which find their way direct to Moscow and the larger cities, the entire trade of the district is in the hands of local middlemen. Many steps have been taken with a view of ameliorating the lot of the cottager and of giving him a larger share in the product of his industy, and individual zemstvos, as that of Nijni Novgorod, by the opening of industrial schools and workshops, founding "artels" (workmen's societies), establishing depots for the sale at cost price of the raw material required by the craftsman, and also with money grants for the maintenance of these institutions, and to provide medical aid to the district, have done much to support and encourage the cottage industries in their own governments. In view, however, of the large population engaged in this type of industry, unity of action and larger grants than the individual zemstvos are capable of supplying are indispensable, and the central Government is being called upon to assist in the work.

TRADE BETWEEN PERSIA AND INDIA —THE NUSHKI-SEISTAN ROUTE.

A few years ago, during Lord Curzon's Viceroyalty of India, the Nushki-Seistan trade route was organised for the purpose of providing an outlet by land for the trade of Western India, and a direct means of interchanging the products of Persia and India. Mr. Edward Penton read a paper on this route before the Indian Section on December 5, 1901, (see *Journal*, vol. l., p. 65). Major Webb-Ware, the Political Agent at Chagai, who did so much for the opening up of the route, has just written a report on the statistics of the trade passing over the route during the year 1906-07, from which it appears that there was a considerable falling off in the figures as compared with those for 1905-06. The exports in the year 1906-07 were Rs. 6,15,266, and imports Rs. 6,28,634, or altogether Rs. 12,43,900, being a falling off of no less than Rs. 3,01,081, this being manifested almost wholly in the exports, for the imports showed a slight increase. The export trade passing through Nushki, which, it may be observed, is in the nature of a frontier mart, goes to Afghanistan, Persia, and Baluchistan, and though, as already mentioned, the exports to all these countries have decreased, the falling off is far larger in the case of Persia than in the other two. Major Webb-Ware ascribes this partly to the outbreak of plague in Seistan, and consequent preventive measures, but some other causes may have contributed to the unfavourble result. The chief decrease, so far as Persia was concerned, was in indigo (Rs. 89,820), hides and skins (Rs. 19,127), and tea (Rs. 7,255). In the exports to Baluchistan the decreases were observable in cotton piece goods, grain and pulse, and provisions, in the order named. In the imports from Afghanistan and Baluchistan there were slight increases, but the Persian trade was so bad that the imports fell off as well as, though not to the same extent as, the exports. The decrease was greatest in the case of turquoises and precious stones, and one explanation of this is that advantage was taken of the parcel post to transmit these stones under cover, and that they thus escaped registration.

As regards the question of carriage, which depends on the supply of camels, some difficulty is experienced on the fact that the western part of the Nushki-Seistan trade route traverses practically uninhabited country, where in summer grazing is scanty and the heat excessive. But by dividing the route into two sections, and establishing the head-quarters of the western half at Robat, under a separate camel contractor, working under the British Consul, improvement in the trade is anticipated.

The horse trade shows no signs of animation. Persian horses are not regarded favourably in these days by our native cavalry regiments, and prices in Khorasan are out of proportion to the quality of the animals. Formerly in the days of Turcoman raids it was essential for every Persian village to have a body of well-mounted men, but this necessity has of course long ceased to exist.

To sum up, the trade returns for the year appear at first sight discouraging, but when it is borne in mind that riots broke out in Seistan in consequence of the plague preventative measures, the exceptional features of the year will be better understood. Quarantine stations and plague cordons were established on the main routes connecting Seistan with Meshed as well as Seistan with Quetta, and many carriers took fright and declined to fulfil their engagements and proceed beyond the frontier. No case of plague had at the date of the report appeared in South-Eastern Persia for upwards of eight months, the cordons are being withdrawn, and there are several signs that trade is likely to revive. It would be interesting if in his next report Major Webb-Ware were to furnish information regarding the operation of the Persian Custom duties, which are alleged to be unfairly enhanced against British Indian trade, and which may be responsible for much of the decrease noted in the present statistics.

HOME INDUSTRIES.

Coal and Ships.—The exports of coal during the half-year ended June 30th last show considerable expansion. They amounted to 30,802,213 tons, as compared with 27,587,700 tons in the corresponding months of 1906. These figures include coke and patent fuel. The exports of coal alone total 29,675,774 tons, as against 26,548,462 tons in 1906, an increase of no less than 3,127,312 in six months. The increase is largely due to the German demand, it being to Germany direct 703,150 tons, the shipments to Holland showing an increase of 837,174. The abnormal condition in Germany, whose industrial consumption and interrupted production have compelled her to import larger quantities from the United Kingdom, has helped the industry here, and quickened shipments to France and elsewhere. The bad weather, too, has prolonged the busy season. A large number of contracts have still to be covered. A good deal of small coal is contracted for to be shipped to German ports; France is contracting largely for gas coal, and the pressure of orders for Welsh steam coal has been renewed. All this points to continued activity in the coal trade, but signs are not wanting that this abnormal prosperity is nearing the end. American coal is now cheaper f.o.b. port of shipment than Welsh coal, and is being pushed even in the Mediterranean. The Italian navy has been buying American coal, and the Italian State railways are said to be negotiating for a supply from the United States. The cost of production is beginning to tell. High prices here f.o.b. for steam coal, and high outward freights, means dearer "bunker" coal and there is no likelihood of the cost of production lessening. It may be some little time before we have a statutory eight hours' bank-to-bank day for mining, but the pressure upon the Government to carry it is great, and the evidence taken before Mr. Russel Rae's Committee proves it would materially raise the cost of production. But it is not only shortened hours of work that is likely, the Miners Federation of Great Britain are about to convene a national conference for the purpose of organising a comprehensive scheme intended to raise the basis upon which the minimum wage shall hereafter be calculated, a charge which, if brought about, must of itself seriously effect working costs. The outlook cannot be viewed with unconcern by the shipping industry. It was demonstrated to the Departmental Committee that the proportion which coal bears to the working of steamers ranges from 25 to 30 per cent. in the case of tramps, to 40 to 45 per cent. in the case of mail steamers, and to close upon 50 per cent. in the case of the very large and fast steamers. It has been estimated that every shilling per ton added to the price of coal means £1,000,000 per annum added to the cost of operating British shipping, and if this estimate is near the mark the working costs of British steam shipping is now from £3,000,000 to £4,000,000 per annum more than they were in 1905, without any compensation in the way of higher rates of freights; on the contrary freights are low and likely to remain so, and working costs are not likely to be lessened but rather increased by the new Merchant Shipping Act and the Workmen's Compensation Act.

Railways and Waggons.—The railway regulations in regard to private owners' waggons have now been revised by the Clearing House, and the new rules came into operation on August 1st. They stipulate that siding rent will be chargeable to the owner, or his agent, in respect of standing room for any waggon detained at a station or siding for repairs at a rate of 6d. per waggon per day, exclusive of Sundays, and for shunting such waggons into and out of the premises of private waggon repairers a mininum charge of 6d. per waggon will be made. Other clauses are designed to protect the companies against claims for delay due to causes other than negligence on their part, and the notice containing these alterations also states that they will not be liable for any injury that may occur to waggon repairers, who will be required to execute an indemnity before they are allowed to work on the companies' premises. The Association of Private Owners of Waggons is at present engaged in litigation with the railway companies as to the whole question of siding rents, and the Courts are to be asked to define the respective rights of owners and companies in the matter of private railway waggons.

Cotton Bills of Lading.—During the present year much disatisfaction has been expressed with the way in which through bills of lading for raw cotton are issued in the United States. It would seem that a custom has grown up under which bills of lading can be obtained for cotton as having been received at the port of shipment for export by a specific steamer, when in fact the cotton is up country, and owing to the congestion on the railways, likely to remain there for some time, cases having occurred where it has not been delivered at the port of destination in Europe until three or four months from the date of the bill of lading. The result is much trouble and loss to importers, and the principal cotton associations and other organisations of merchants and buyers have been trying to find a remedy. A conference has been held at Liverpol on the subject, and it is hoped that good may come from it. Referring to this important matter, the Liverpool Cotton Association has published the following comments:—"1. The objection to the so-called 'ocean bill of lading' is that in the majority of cases it erroneously purports to show actual delivery at a port of goods which are still in transit, and that the holder of such bill of lading has no proper security, because (*a*) he is entirely dependent upon the honesty of the ship agent in the port of shipment, to whom the goods are consigned, and who has entire control of them on their arrival at the port; (*b*) even if the signatory of such bill of

lading is an 'authorised agent' of a steamship line the latter assert that they could legally disclaim responsibility if it could be proved that their agent had acted *ultra vires.* (2) The remedy proposed in Galveston consists in a so-called 'exchange bill of lading,' *i.e.*, a receipt given by the ship agent for the 'railway bills of lading,' and a promise on his behalf to forward by certain steamer or steamers the goods enumerated therein. Some suggestion is made that such bills of lading should be certified by a railroad clearing-house. Objections are raised to the 'through bill of lading' (apparently on behalf of Texas bankers) on the ground that it does not give a sufficient guarantee, because under this bill of lading the responsibility of each carrier ceases as soon as the goods have been turned over to the next carrier, and it is, therefore, stated to be extremely difficult to trace the goods, and 'practically impossible to prove the liability in any Court.' (3) The European importing interest contends (*a*) with regard to the 'exchange bill of lading' that the only advantage of this bill of lading lies in the fact that it frankly states that it is not a port bill of lading, but only a receipt for certain 'railway bills of lading,' but that otherwise the objections to the ocean bill of lading also hold good in this case; (*b*) with regard to the through bill of lading, experience in the past has shown that there has been no difficulty in attaching full responsibility to any individual railway company which has not fulfilled their part of the contract; (*c*) that the importers therefore consider that a through bill of lading which stipulates that the goods are to be consigned to the care of the ship at port of shipment, or to an agent for whose acts the shipowner will accept full responsibility, gives a sufficient guarantee of continuity of responsibility from the time of shipment in the interior until delivered at the European port, and is therefore preferable, as a collateral to be attached to an interior bill of exchange, to both the suggested new exchange bill of lading and to the present ocean bill of lading."

The Railway Companies.—It is not surprising if investors in railway stocks are seriously perturbed at the continuous decline in values. They have been accustomed to regard stocks of the more prosperous railway companies as among the best of securities, and they consider it strange that, at a time when the trade of the country is said to be exceptionally active, the capital value of their railway investments is lower than for many years past. Take for example the consolidated stock of the London and North-Western Railway Company, not only the most important company in the kingdom, but one of the best managed. In 1906 the average price of this stock was 155¼; last week it was quoted at only a fraction over 140. Last year's quotation represented a most serious fall as compared with say that of 1900 when it was 186¾, and the dividend distribution was lower, but the fall has continued, and it would be a rash prophet who said that it will not go further. The decline in market values is not invariably in accordance with common sense, but it may be assumed that among many causes prejudicially affecting railway stocks at the present time the price of coal and the agitation among the men for higher wages take foremost place. It is understood that the railway companies will have to pay something like 3s. per ton advance on the last contract prices. That is a serious addition to working costs. According to the Board of Trade returns for 1905 the consumption of coal for locomotive purposes on the railways of the United Kingdom for the year amounted to 11,593,758 tons, and this quantity at 3s. per ton represents £1,739,064. The effect in increased cost of 3s. per ton advance in price of coal used by the London and North-Western Railway Company means £203,022. Then it is considered probable that the railway companies will concede at least a part of the men's demands in the matter of wages, which means another considerable addition to working expenses. Add to this the growing requirements of the public where speed, service, and comfort are concerned, and some of the causes making for the depression of railway stock values are disclosed. But when due allowance is made for these and other factors the present level of quotations would seem to be unduly low.

GENERAL NOTES.

DRAWING AND ART TEACHING CONGRESS, 1908.—The third International Congress for the Development of Drawing and Art Teaching will be held in London during the first week of August, 1908. Two previous Congresses have been held, the first in Paris in 1900; the second in Berne in 1904. The Congress, it is expected, will bring together representatives of drawing and art teaching from all parts of the globe, and in connection therewith a large and comprehensive exhibition is proposed, which will show the methods of art teaching pursued in the various countries of the world. Applications for space and enquiries have already been received from Germany, France, Russia, Italy, Austria, United States, Egypt, India, New Zealand, Newfoundland, and many other places. Among the list of Vice-Presidents are the ambassadors for France, United States of America, Germany, Italy and Austria-Hungary, and other distinguished authorities. The chairman of the British Committee is Sir John Gorst, and the vice-chairman, the Earl of Carlisle. The organising secretary is Mr. C. M. Mathews, whose address is at the office of the Congress, 151, Cannon-street, London, E.C.

Journal of the Society of Arts.

No. 2,856. VOL. LV.

FRIDAY, AUGUST 16, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

EXAMINATIONS.

The results of the Intermediate Examinations (Stage II.) were published last week, and copies for distribution to Candidates have been sent to all Centres. The results of the Elementary Examination (Stage I.) will be published at the end of this month, or early in September.

PRIZE FOR INDUSTRIAL HYGIENE.

The Council of the Society of Arts are prepared to award, under the terms of the Benjamin Shaw Trust, a Gold Medal, or a prize of £20.

The medal, under the conditions laid down by the testator, is to be given "For any discovery, invention, or newly-devised method for obviating or materially diminishing any risk to life, limb, or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means."

Intending competitors should send in descriptions of their inventions not later than December 31st, 1907, to the Secretary of the Society of Arts, Adelphi, London, W.C.

Such descriptions may be sent in under the inventor's name, or under a motto, accompanied by a sealed envelope enclosing the name, as preferred.

The Judges will be appointed by the Council.

The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the Judges nothing deserving the full award is sent in.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

ROMANESQUE ORNAMENT.

By F. Hamilton Jackson, R.B.A.
Vice-President of the Society of Decorative Designers.

Lecture II.—Delivered March 4, 1907.

It is impossible, in the short time at our disposal, to go over the other countries of Europe in even as full a manner as France has been treated, but we may have a few interesting examples from Italy. The church of St. Michele, Pavia, shows by the differences of its walling that portions of it belong to three periods, re-buildings, no doubt, after fires and sackings of the town. The bands of carved ornament show the use of older material also, the irregularities in the widths of portions which should match, as well as the difference in the style of the fragments, making it impossible that they can occupy their original position. There is a mixture of motifs with a Byzantine origin, of figures of varying degrees of incompleteness, some of them bearing a resemblance to the barbarous Irish figures, of monsters and of hunting scenes, and in the side doors patterns of a much earlier type, mixed with Roman and Byzantine details, such as the rings containing half-figures supported by angels, and the vase flanked by doves. At S. Maria, Maggiore, Barletta, the horizontal lines of fighting figures are twisted round the archivolt, which they fill, the proportions being stumpy and the relation of human to animal or bird figures unnatural. This church has an extraordinary mixture of Lombard work with Oriental-looking pierced marble grilles, and an eastern end which is French Gothic in

style. At San Leonardo, between Siponto and Foggia, is a very beautiful door with fine arabesque scrolls, among which birds, beasts, and monsters are intertwined, in almost perfect preservation. The convent belonged to a German military order, but I cannot see any specially German character in the design, the sharp thistly foliage being rather Byzantine. The figures show the usual inadequacy—note Balaam and the Angel and the Adoration of the Magi on the caps—subjects which recur at Monte Sant' Angelo in the same positions. The beautiful ease in the flow of the curves shows that this is rather a late example. Compare it with this very fine door at Bitonto which M. Bertaux gives to Frederick the Second's time, partly on the strength of the eagle above. The eagle appears to me to be a later addition, and the arrangement of the pillars with griffins above and lions below is exceedingly like that at Ruvo, so I should be inclined to put it a little earlier. This window from S. Abbondio, Como, I think is difficult to surpass as a piece of ornament. The spaces are well-filled and balance quite satisfactorily without being at all alike, and the contrast of the flatly-treated carving with the twisted moulding and colonnettes is very happy. The only drawback is that the little eagle caps are scarcely important enough. The whole of the Cathedral of Modena is worthy of attentive study, and I show you now one of the south doors, the Porta Principe, with the story of S. Gemignano on the lintel, and a very fine and inventive pattern of lines which flow and return and interlace, with figures among the arabesques upon the jambs and archivolt, the work of Nicholaus probably, to whom so many of the fine portals are due, as at Piacenza, Ferrara, and Verona. At Montefiascone, near Viterbo, is a very interesting church of the eleventh century with two storeys communicating by a well as in the chapel of the castle of Landsberg, and here the carving shows Lombard influence very strongly, both in the creatures themselves and their actions, while the plan with a pillar and a pier alternately is also Lombard. Yet certain of the ornamental forms are based on Byzantine data, and may be parallelled by others found in the south of France. And in this capital from the cathedral, Veglia, the place of the usual leaves is taken by gambolling beasts of pronounced Oriental type and birds facing each other within semicircular-headed forms, with the usual grooved volutes, while a band of scroll work runs round the neck. This arrangement of ornament within semicircular-headed forms is found on the Sassanian vase already referred to. Other caps in this cathedral are fine examples of pure Byzantine work, and there is one which is an exact replica of one at Spalato which formed part of the campanile. The east window of the cathedral, Bari, is one of the finest examples of carved ornament of the end of the twelfth century known to me. The elephant supporters below the shafts and the man and woman sphynges above are carved admirably, and the animal forms combine well with the arabesques in the panel below. This kind of window in the screen wall between the towers which flank the apse is peculiar to the Apulian churches, and another example, equally beautiful, looks over the harbour at Trani from the church of Ognissanti. This door of the cathedral, Foligno, so closely resembles work at Bevagna signed by two Ghibellines, Rodolphus and Binellus, as to make it pretty certain it also is theirs. The projection of the symbols of the Evangelists from the inner border of the arch is very curious. The pattern on the left inner jamb occurs on a church at Toscanella and the archivolt is divided up into rectangular panels as at S. Michele Pavia—classical influence is evident in some of the details. The little arcade for the ceremonial of Palm Sunday occurs on a larger scale in the thirteenth century addition to S. Pietro, Toscanella—where is a very fine wheel-window flanked by two of two lights with a broad band of carving round them which recalls the work at S. Pietro, Spoleto, and S. Maria Impensole at Narni. The interior of this church is interesting both on account of the ritual arrangements and for the carved ornament. Some of the caps resemble in line and spacing other examples in France, and there is a good deal of flat ornament of the eleventh century about the choir, which was recast at that time, when a crypt was made. A little vestibule to the crypt with an altar in it has one most curious cap with the lines of the volutes continued across the front and crossing, as in certain caps found both in Etruscan tombs and in Crete.

In the Abruzzi the sculptors appear to have preferred high relief to flat carving, as this ambo at S. Clemente in Casauria shows, a quite typical example. The Byzantine influence is strong in the mode in which the stone is cut with the effect of piercing, and in the arrangement and choice of some of the details, though the planning of the ornament is original.

But the Oriental influence in several places is still stronger, and at Cugnoli and Moscufo one finds definitely Arab motifs mingled with the ornamental details. In Apulia the sculptors of church furniture preferred to work in marble, with a flat treatment and a good deal of inlay, as in the fine ambo at Bitonto made by Magister Nicholaus, in which inlays of coloured marbles and vitreous pastes are used. There is another in the church which has gilded patterns on dark blue glass in the interstices of interlacings; and at Canosa is one which resembles examples on the Western Coast, while quite a number of episcopal seats exist with flat Byzantine-looking ornament carved in white marble. The patterns on the narthex of S. Maria, Pomposa, are of terra cotta, and the dislocations show that rebuilding has taken place. Exactly similar patterns decorate the great Campanile, which has an inscription upon it dated 1063; but probably the marble has been encrusted in the wall as the fragments have been in the wall of the narthex, for a date of 1115 is given by an inscription upon the latter, which agrees better with the style than 1063.

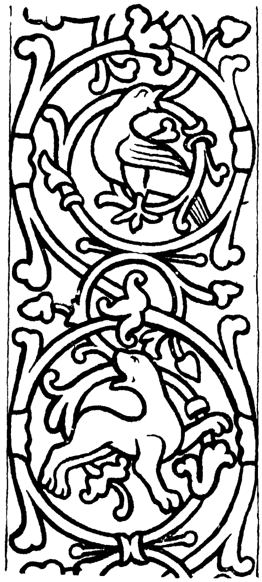
To return for a short time to France, to the cloister at Moissac, the capitals in which are among the finest productions of French chisels of the period. The buildings carved upon them have round arches, though the structural arches are pointed, a discrepancy which suggests a rebuilding at some time. The columns are of four different kinds of marble, but the caps are of limestone, grey or yellowish, and probably date from the second half of the twelfth century, before Richard Cœur de Lion took the town in 1189, though the cloister may have been rebuilt about 1271, at which period the pointed arches were probably added. Some of the caps show animal and bird forms, arranged very ingeniously to produce ornamental grouping of lines, and the contrast between the bell of the capital and the abacus is always marked by a difference in the scale of the creatures or of their kind, or by the purely ornamental arrangement of them, and in many cases simple ornamental forms are used, the abaci being in general treated most simply where the interest of the ornament upon the cap is greatest. The single columns seem scarcely thick enough to satisfy the eye as compared with the wide-spreading of the caps — a legacy from the practice of the Lombards, though the large sloping surface is covered with cleverly-designed ornament; and the greater solidity of the angles, where coupled columns flank the pier, is more satisfactory. Most of the heads in the figure-work have been knocked off; the one now before you, which represents Daniel among the lions, and is rather better preserved than most, wlll show that as usual the accomplishment of the ornamental carver is greater than than that of the figure sculptor. A cap in the museum at Toulouse has this subject with an absolutely similar figure of Daniel, and the side of the porch, which has the subject of the Rich Man and Lazarus, shows the rich man with the same Jewish kind of cap. M. Marignan relies upon this detail to prove that the two are contemporary, but the capital at Toulouse is thought to be earlier than those at Moissac. The inscription in the cloister gives the name of Abbot Ansquetil as builder (1085-1115), but the caps have been ascribed to Abbot Roger (1115-31) whose figure, inscribed with his name, occupies one of the engaged pillars of the external wall of the porch. M. Marignan says the costume is of the last quarter of the twelfth, but the details of furniture, &c., belong to the beginning of the thirteenth century. The ornament, which is cut with great dexterity, may be influenced by Arab work from Spain, by Greco-Oriental objects or Oriental stuffs, while some of the figures show traces of the Gallo-Roman tradition. The Albigensian wars practically put an end to the early Tolosan school. At Moissac there was a destructive fire in 1188. Next year Richard Cœur de Lion took the town, which remained English for eight years. Fifteen years later Simon de Montfort took it and Raymond VI. afterwards punished those who had deserted his cause. In 1229 the town walls were razed, so that it seems certain that the carving must have been done before 1188.

Byzantine art is a complex product based upon Persian, Syrian, and Egyptian design as well as upon the debasement of classic forms. The details of ornament came from Assyria, Phœnicia, and Judæa by way of Asia Minor before the Arab invasions. Such details as the sharply cut and spiky foliage, the galleries over the aisles in the basilicas, the three apses polygonal externally, and a few new iconographic subjects came from Syria. The development of the style was complete in the seventh century, though it is probable that the iconoclastic struggle had something to do with the general preference for ornament in place of figure sculpture which spread over the West also, for protestations against the luxury of the churches and the cult of icons proceeded

from Syria and Phrygia quite early. In the West, Bernard of Angers at the beginning of the eleventh century expressed indignation on seeing statues of gold and silver at Conques, declaring that this pagan custom would be considered sacrilege in countries farther north. The Germanic races appear to have refrained from representing their deities, even in Pagan times, while the French probably owe to the admixture of Latin blood their delight in the use of figure sculpture wherever it is possible to introduce it, and the excellence which has characterised their work of this kind at almost every period.

Constantinople and the cities on the Bosphorus were the rendezvous of caravans from Pontus on the north-east, Armenia on the east, and India and Persia by way of the Tigris and Euphrates, and Jornandes says that Persian products were sold in the Gothic towns on the Black Sea, which were ancient Greek colonies. In the stores, by the side of Hindu, Persian, and Egyptian importations, were the products of the imperial city which had then an enormous vogue. The specialities were woven or embroidered stuffs, jewellery and goldsmiths' work, carvings, enamels, and ivories. The ivory carvers' shops had diptychs, triptychs (a Byzantine invention like a holy door) caskets, and isolated panels which were often applied to book covers. Halitgaire, Bishop of Cambrai, ambassador in 828 from Louis le Debonnaire to Michael le Bègue, brought back such panels with him. In antiquity silk stuffs enriched with ornaments or embroidered came from Egyptian or Asiatic workshops to Eastern Europe, like the royal robes pictured on the Assyrian reliefs and the figured stuffs represented on ancient painted vases. Asterius, Bishop of Pontus, at the end of the fourth century, says in a homily, "They buy eagerly, both for themselves, their wives and children, clothes covered with flowers and offering images of an infinite variety. There one may see lions, panthers, bears, bulls, dogs, forests, rocks, hunts—in a word all that the work of the painter can produce to imitate nature. The most pious of these rich men take subjects from the Gospels." The use of such sumptuous robes continued and spread, and in the eleventh century French and Normans admired the embroidered clothes of the British nobles, and recognised that the English excelled all others in this kind of work. It was soon called *Opus Anglicanum*, and till the thirteenth century the English retained their supremacy in the craft, though the French also thought the Germans good at it. Germans who excelled came to England to learn their trade. Otho III. had a cloak with scenes from the Apocalypse, which was probably worked by the Abbess of Quedlinburg, and the cope which Henry III. gave to the cathedral of Bamberg remains as an example of the excellence of German workmanship, while the Syon Cope and that stolen from Ascoli and restored by the munificence of Mr. Pierpont Morgan bear witness to the English mastery.

FIG. 9.



ORPHREY FROM CHASUBLE OF S. WOLFGANG, RATISBON.

M. de Farcy claims this cope as French work, The chasuble of S. Wolfgang, preserved at Ratisbon, shows ornament of English character (Fig. 9). He was brought up at Reichenau, rose to eminence, becoming Bishop of Ratisbon after going to preach to the Hungarians in 972. He died in 994, and MM. Cahier and Martin say that the braids upon the vestment are of the tenth century.

The splendid dalmatic, said to have been Charlemagne's, but 200 years later than his time, in the treasury of St. Peter's, at Rome, has embroideries of the Transfiguration, Christ in Glory, and the Last Supper. Christ stands by an altar, and gives to six apostles bread on one shoulder, and to six others wine from a two-handled chalice on the other. It is probably Greek work to judge from the costumes. An eleventh or twelfth century cope preserved

at Metz, with eagles embroidered on red silk, is Oriental. On the wings are roundels containing griffins, an eagle stooping on a hare, crescents and liney scrolls in gold, white, green, and yellow. It resembles Frederick II.'s mantle at Vienna. Mgr. Wilmowsky found in tombs of archbishops of the twelfth century at Trèves, vestments with patterns of this kind based upon Oriental motifs. Diamonds filled with figures of standing lions, circles containing griffins dancing back to back, and peacocks face to face standing in the spaces between the circles, a space which in other parts of the design is filled by a pattern of palmettes of a quite Greek shape. The ring of Ethelwulf, father of Alfred, preserved in the British Museum, shows upon a mitre-shaped surface, in niello, a kind of tree bearing two circles containing quatrefoils, probably symbolising the host, flanked by two peacocks bearing a close resemblance to Oriental textile figures.

FIG. 10.

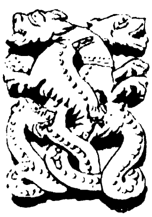


FIG. 11.

At Toulouse are carvings apparently copied from Byzantine embroideries with pearled scrolls which interlace, and on the façade of S. Gilles are roundels which resemble textiles of Cappadocian origin. From Naples southwards to Salerno, ninth century plaques still exist with winged horses, griffins, and peacocks within circles, or like this one from Atrani, all of which are quite evidently Oriental in their derivation. The well-known subjects on the screen at Torcello, which are early eleventh century, also show the same feeling with greater mastery, and bear considerable resemblance to the panels encrusted on the cathedral at Athens, which M. Bertaux claims as being based on Sassanian motifs. At S. Pietro in Civate are incised slabs with monsters of quite Oriental type upon them, and at Ancona and Venice are other slabs, both incised and in relief, which show Oriental influence quite as strongly, while one of the mosaics at Germigny-des-Prés was asserted by M. Courajod to be a copy of a Persian miniature. At S. Sernin, Toulouse, a cap below the statue of S. James shows that the sculptor copied an ivory which was probably Hindu from the types of feature and costume, and in the nave of the cathedral, Bayeux, a series of panels is placed upon varied diapered grounds in the spandrils of the arcade which also appear to have been copied from Hindu or Chinese ivories or bronzes, the

FIG. 12.

FIG. 13.

monsters retaining a great deal of the original feeling (Figs. 10 to 15); and on one of the arches pendant pine cones occur as an ornament, which are also found upon capitals in the South, as on this one from the triforium of S. Sernin, Toulouse, upon another in the eleventh century church of S. Adriano, in Calabria, and elsewhere. Now in the British

FIG. 14.

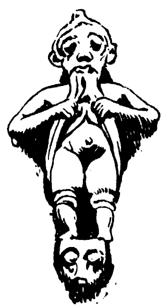

FIG. 15.

CARVINGS FROM BAYEUX CATHEDRAL.

Museum there is a Syrian cap from the Harâm-es-Shereef, Jerusalem, which has this identical feature coupled with the usual thistly foliage of the sixth century, another instance of details of which the origin is demonstrably Oriental. It is much the same in Spain. The chain of the votive crown of Reccesvinthus, now in the Musée Cluny, is composed of links of a quite Hindu shape, as is one of the chains of those in the Armeria

Reale at Madrid. In the museum in that city is a crucifix brought from Leon, made for Ferdinand of Navarre, who died in 1065, and his wife Sancha, sister of Bermudo III. of Leon, who died two years later. The patterns of the ornament show Oriental influence strongly both on the front and the back, which I am able to show you, and the difference between the struggling figures of the front border and the developed ornamental forms of the back, some of which appear to be quite twelfth century, is striking. There is the usual inferiority in the treatment of the principal figure, but the Evangelistic symbols on the arms are satisfactory from the point of view of design, filling the spaces well. In the treasury of the Abbey of Silos is an extraordinary chalice of rather earlier date, ornamented with arcading of horse-shoe arches in filagree and precious stones which is supposed to be the work of a Moorish slave of the abbey, as the only way of explaining the curious use of Arab forms. The fine twelfth century Limoges retable, once belonging to the same abbey, shows round-arched canopies and Byzantine-looking figures, with a running ornament which is exactly like a Coptic ornament on the abacus of a cap at El-Azhar, Cairo. The same pattern also appears several hundred years later in the mosque of Sultan Hassan. The relations of Limoges with the East are known. Between the Caliph of Cordova and the Emperors of Constantinople there were were also continuous relations, and Greek artists and savants often went to Spain. From other parts of Europe pilgrimages to Jerusalem were frequent, which went by way of Constantinople, while embassies were sent from one side or the other between Germany, Italy, and France, and Byzantium.

The sacred crown of S. Stephen, kept in the castle of Buda-Pesth under seven locks, the keys of which are kept by seven different magnates, is an instance of the costly gifts from Byzantium. It was given by Michael VII. (1071-8), and his son, Constantine Porphyrogenitus, to Geysa I. of Hungary, in consequence of a defeat of the Greeks and Bulgarians, in which Geysa showed so much bravery that Michael sent an embassy to conclude a treaty. Geysa then became king, and the crown was, no doubt, sent as a present. Three of the enamelled plaques bear figures of the monarch. It is impossible to see this crown, but there are in the museum fragments of another, made for Constantine Monomachos, which had similar plaques of cloisonné enamel.

The two countries which were most directly affected by Byzantine influences were Germany after the marriage of Otho II., and Italy in general during the later exarchate, and specially in the south-eastern part, which was governed from Constantinople, except for certain intervals, till the Normans established themselves in Apulia, in the eleventh century, where Greek was the language of the people, and the church looked towards Constantinople and not towards Rome. Here the paintings of the Basilian monasteries and grotto churches show that an original civilisation on Oriental lines was developed quite early; the influence was not the effect of a domination imposed on subject peoples, but the natural expression of a kindred race. In Rome itself the Byzantine influence continued till the end of the tenth century, largely through the Greek popes, who employed Oriental artists to decorate the churches, and the crowds of orthodox monks who fled before the Arab invasions of the seventh and eighth centuries. At Ravenna, a quarter in the city was inhabited by Armenians, in the ninth century a virile and powerful race, and Greek soldiers formed part of the garrison. Syrians were so numerous that they were able to nominate one of their number for the episcopal dignity during the time that the Exarchs ruled. The Byzantine influence was mixed with Lombard, for the powerful duchy of Benevento ruled a great part of South Italy for more than a century; and at Brindisi, at Benevento, and Ascoli are remains of buildings of that period. The church of S. Benedetto, Brindisi, is one of these buildings, a good deal altered in later days, but still retaining portions of the old work. It is the south door of this church at which you have been looking, built of ancient fragments at a later date, and this is the cloister, which is very primitive in its construction, though the small arches are grouped beneath discharging arches which take the weight of the wall to the piers. The curious capital with the beasts back to back is an earlier form of one of the fine capitals in the external gallery of the matroneum of the Cathedral of Bitonto, a work of much later date, ascribed to the period of Frederick II., but probably a little earlier. Here there is a decidedly Indian flavour in some of the ornaments, such as the leaf-shaped projections forming pseudo-cap to the second column, and the band round the nearest one, mixed with reminiscenses of classical and Syrian ornament. At Benevento there is a cloister which is a good deal like S. Benedetto,

Brindisi, belonging to the church of S. Sofia, also a Lombard foundation. It was re-built in the eleventh century, but a good deal of the old material was used, and you may see by the shape of the super-abaci, which are of the true Lombard type, and by the character of the carving that the old traditions were not abandoned. At the castle of Quedlinburg, in the atrium to the chapel, there are colonnettes and caps resembling these in character, and showing that Lombard influence had some hand in forming the German Romanesque. Another Lombard feature which one sees continually in the earlier German churches is the external gallery, probably a development of the open loggia. The laws of Liutprand mention dwarf colonnettes of four or five feet high, which could only have been used for cloisters or for such galleries, whether with arches or without, as in the apses of S. Frediano, Lucca, and in Pisa Cathedral, and in the cloister of Voltorre, the village from which the artist family came which furnished architects for 200 years to the cathedral, Modena. This view of the interior of that building shows the entrance to the chapel beneath the choir, constructed with portions of the ancient ambo of which other portions may be recognised in other parts of the church. Such lions, or griffins, are met with at the doors of churches all over Italy during the twelfth and thirteenth centuries, and have had all kinds of symbolic meanings attached to them. Outside this cathedral they occur, both at the south, west, and north doors. A reconstruction is shown by the difference of size of the lintel and the archivolt of the north door. On the lintel are subjects from the bestiaries, including the charity of the fowls to the fox in affording him Christian burial, who requites them on the right in the usual manner of the world. Round the archivolt is a subject of knights besieging a castle, one of whom is titled "Artus rex Britaniæ." The Arthurian epic, like that of Roland, often furnished subjects for the decorator. At Bari it appears on the archivolt of one of the side doors of S. Nicola, which has evidently been altered or restored as the dislocation of the design at the springing of the arch shows, where the two subjects from the labours of the months have been put in. The beautiful arabesques are the work of a Greek, named Basilius, or at least a man of Greek extraction, while, close by, the west door is signed by two Comacines, Ansaldus and Taddeus, showing that the same amalgamation of the different styles was proceeding here where Byzantine influence was so strong; and it is curious to note that in the door to the left in the same façade the Comacines use the classic egg and tongue; and you may also see the Byzantine ball flowers and the spiral grooved form (an Eastern detail), while upon the jamb there are figures of warriors fighting among the arabesques, no doubt copied from some ivory casket as in Barisano's work. The west door of the church of Ruvo is I think the finest example of the result of the amalgamation of the styles in Apulia. Parts of the church are of the period of Frederick II., but there was an earlier building, and it seems probable that the doors belonged to it, both from the style and from the fact that they seem out of scale with the rest of the façade. Here the arabesques run without a fault and the surface is enriched without being overloaded, and though the figures are rather poor, as usual, they are not very conspicuous. A door of something the same character enriches the west front of S. Maria in Piazza, Ancona, and is dated 1210 and signed by the sculptor Philippus. It shows the same, or even greater, inability to carve the figure coupled with complete mastery over both the design and execution of the ornament.

On the other side of Italy also Byzantine influence was fruitful in the development of ornament. While the frescoes in the chapel of S. Laurence at S. Vincenzo, Volturno, are based on the same models as the miniatures in the Carolingian MSS. and resemble them in design. In the MSS. at Monte Cassino there is the same mixture of interlacings, monsters, and foliage scrolls as in the Winchester work, but less tastefully arranged and quite 100 years later in date. The great developement occurred after Desiderius brought over the Byzantine enamels, which suggested improvements in colour as well as in the composition of the subjects. The flowers and scrolls of the big initials in the Vatican Bible, M. Bertaux says, are exactly like the engravings filled with a black mastic which decorate the bands of marble on the walls of the church at Daphni, and one MS. signed by a monk named Leo (1072) and with a drawing of him on his knees before S. Benedict and many miniatures, is so Byzantine in style and shows such an advance in drawing and conception, that it is probable that the miniatures were copied from a frontal show ing the miracles of S. Benedict in cloisonné

enamel made at Constantinople by order of Desiderius. He engaged Lombards and Amalfitans to build and then required men from Constantinople to decorate, "who brought the arts forgotten in the west; mosaic of enamel and of marble, using both figure work and geometrical decoration." Much of the magnificent goldsmith's work for the sanctuary was made in Constantinople, but a good deal was executed in the monastery in imitation of the Byzantine treasures, for he ordered that the monks and the young novices should be taught the most various kinds of art: "to work in silver and gold, in iron, glass and ivory, stone, wood and plaster." Here we see the same kind of universal activity as reigned at Hildesheim under the instruction of S. Bernward.

The earliest of the bronze doors which still exist in the south of Italy were importations from Constantinople, commencing with those of the cathedral, Amalfi, which were seen in their present position by Desiderius in 1062, given to the church by Count Pantaleone. Members of his family gave those at Atrani, S. Paolo fuori, Rome, of which only a few poor remains escaped the fire, Monte S. Angelo and Monte Cassino, the last named being practically unornamented. In these doors the figures are incised on the bronze, and the lines filled either with silver or with a coloured mastic, and some of the panels have crosses cast and chased applied to the surface which bear great resemblance to others, nearly contemporary, at S. Sophia, Constantinople. The doors of the Cathedral, Salerno, given in 1099 by Landolfo-Butromilo and his wife, are similar, and at S. Mark's, Venice, is a pair of doors of the same kind brought from Constantinople, and another pair made in the twelfth century in that city in imitation of them. These doors are all inscribed, so that there can be no mistake as to the time and place of their manufacture. At Troja are two very fine doors made by Oderisius, of Benevento, in 1119 and 1127, which combine the Byzantine technique with a feeling for grotesque and relief work, and with engraved patterns of a Western type; and at Canosa are two remarkable doors made by Roger, of Amalfi, about 1115, on which the applied flat ornament is quite Saracenic, while some of the figures were executed in the usual Byzantine manner and others cast and applied. Amalfi had a flourishing commerce in the early mediæval period. While in Salerno Arab science came in contact with Christian and that of the West, Amalfi was the centre of exchange for Eastern and Western merchandise. The Arabs brought thither Oriental manufactures and received in exchange Western products; and the Amalfitans carried Western manufactures to the maritime cities of North Africa and Syria. They also had relations with the Greek ports, bringing especially the purple robes which the Greek nobility used to wear. It became the special emporium of the silks of Greece. Amalfitans were also established in Constantinople, Sicily, and other places. The beautiful marble ambos of the twelfth century, of which this at Salerno is an example, are the product of this mingling of Oriental influences with the Lombard. It was made for Romuald the Salernitan bishop, and councillor to William I. and II. of Sicily, who spent a great part of his life in Palermo, and, no doubt, employed Saracen workmen to fulfil his commission, though the sculpture of the Easter candlestick especially shows the chisel of a Campanian sculptor. The fine doors at Benevento, of about 1150, show Byzantine influence in the design of the subjects and in many of the architectural details, but combined with a study of nature and a variety in the arrangement of poses which at first sight seem alike, which show that the design was not an affair of carrying out a receipt. The doors made by Bonannus of Pisa and Barisano of Trani, which stand near each other in the Cathedral of Monreale, show considerable feeling for relief. In the west doors at Trani and Ravello Barisano employed the same moulds as at Monreale with somewhat different surroundings, basing many of his models on the panels of the Byzantine ivory civil caskets, on which figures of warriors fighting, &c., are common. The ornament between the panels is also quite Oriental in its suggestion frequently, and this detail from the door at Ravello shows how the various pieces were combined. He was a commercial craftsman and thought nothing of repeating the same panel over and over again in the same door—indeed both in this door and in that at Trani the two leaves are repetitions of each other, and the form of the panels at the top of the door (which is square-headed) shows that it was originally designed for one which fitted within an arch—the door at Trani in fact. Bonannus also did not mind repeating the general arrangement of his door, and that at Monreale is very like that at Pisa, with the opposite fault, for Pisa must have been the original with a square head and

long panels at top and bottom ; at Monreale, part of the top panel is hidden by the arch. Herr Graeven made a curious discovery at Pesaro of an ivory of Adam and Eve being driven out of Paradise, which is identical with some little figures on Bonannus' door at Pisa, and which makes it certain that ivories were used as models by the Italian bronze workers ; and by further discoveries has shown that the ivory workers sometimes copied miniatures. He found in the Museum at South Kensington a panel with two ends added to a central portion. The centre was the reproduction of a miniature from the Joshua roll in the Vatican Library, a MS. of about 500, while two figures on the piece added to the right were taken from another miniature in the same roll. One of the panels of the cover of the Psalter of Charles the Bald and a panel in the Zurich Museum also show the use of miniatures as copies, in this case from the Utrecht Psalter; and the cover of the Veroli casket he shows to have been put together from various classical sculptures and mosaics, specially the Europa corner from a mosaic found at Palestrina and now in the Barberini collection at Rome.

The northern tradition is seen in the doors of S. Zeno, Verona, which were probably originally made in Saxony and show great resemblance to work at Hildesheim, Augsburg, and Nijni Novgorod, at which last-named place there are doors which came from Magdeburg. These doors of S. Zeno were burnt in 1160 and restored, and additions by a third hand, probably a local craftsman, may be recognised. The piercings in the dividing rolls are probably a reminiscence of the cloisonné glass and garnet work which the early Goths practised—the plate prepared for the jewels. The German influence in this part of Lombardy was very strong; it was reunited to the Empire by Otho I., and in the lists of monks and nuns on the various religious foundations names of German or Lombard derivation are far more numerous than Italian names.

Architectural ornament, both painted and carven, appears generally to have developed in accordance with the progress in the Scriptoria, though it is questionable in some cases whether the design of the goldsmiths' work influenced that of the MSS. or whether the reverse was the case. At any rate details of ornament which appear in architectural decoration in the twelfth century are to be found both drawn and worked in metal at an earlier date. At Reichenau and Ratisbon were schools of illuminators whose designs were used for wall paintings, and in the MSS. the ornamental details show the plan of Romanesque scrolls, with Byzantime forms in the accessories of the miniatures, with Lombard interlacings, and in one case at least with a development of Syrian carved patterns of the sixth century. The north door of the Cathedral of Basle, 1010-19 (to which Henry II. presented the fine antependium now in the Musée Cluny), shows ornament which has Eastern suggestion though obscured by restoration. In Frederic Barbarossa's Castle at Gelnhausen, the Oriental suggestion is stronger, the general form of the caps bearing a likeness to Saracenic shapes (as we have found also at Le Puy), coupled with the Byzantine super-abacus elaborately carved. Similar arcades to this one occur at Schloss Münzenberg, Goslar, The Wartburg (which is perhaps the finest example, having several storeys), Wimpfen, Seligenstadt, and in other castles. Frederic went with his uncle Conrad to the crusades in 1147-8, and perhaps this may account for the character of the ornament to some extent. The date is 1170, and there is a curious difference between the extreme richness and elaboration of the ornament of the archivolt of the door to the great hall and the simplicity of that applied to the fire-place. At each side is a carved panel—one has an interwoven pattern met with in Rome in the sixth century, and the other a well-known ninth century pattern of interlacings. The arch of a window opening above and the shafts of the fire-place have a simple zigzag and chevron, and if the two panels were not of the local stone one would suppose that they had been imported in the same manner as Charlemagne imported marbles for his palace at Aachen. On one of the capitals the imperial eagle appears, but it is doubtful whether it has any heraldic signification, for capitals almost precisely similar occur at Toulouse and in other places where there could be no question of imperial rule. The little town has a very fine church of rather a later date, probably about 1220, but the carving retains the Romanesque patterns in the elaborate ornaments of the jambs and archivolts, and gives a very good idea of the richness of the later Romanesque. Here you may still observe an inferiority in the treatment of the figure work to that of the ornament, and a certain stiffness of pose, though it is a great advance upon the earlier Romanesque figure

sculpture; but the carving of the ornament is excellent, and, indeed, has been styled "unsurpassable" by a German art historian.

The Cathedral of Bamberg in its present state dates from the twelfth and thirteenth centuries; the western choir was finished in 1274, a consecration is recorded in 1237, and an earlier one in 1111. To the earlier building the doors at the eastern ends of the aisles belong, one of which has a very beautiful range of capitals with half lengths of saints, forming a kind of superabaci. The other has had figures attached to the columns in imitation of the French portals at a later date; and the fine door on the north with similar figures and a Doom in the tympanum is also of this period, several of the figures being evidently carved by the same sculptor. The grimacing figures, by another hand, show that the French influence had not been fully absorbed, though the capitals are many of them quite excellent in design, but no longer distinctively German in character.

It has been claimed by some German writers that the Romanesque style was firmly established in Lower Saxony in the second half of the tenth century. If that is so, it can only have been as simple construction, for after the Ottoman impulse was exhausted the level of carving was very low until the end of the eleventh century. Many of the examples have been dated too early, and the latest German opinion appears to be that the carving on the Holy Grave chapel at Gernrode, some tombs of abbesses and other carvings in the Schlosskirche, at Quedlinberg, and the figures on the parapet of the West Gallery at Kloster Groningen are the earliest examples extant. These are all of the twelfth century. A good deal of beautiful archaistic work was done in stucco, at Hildesheim, Halberstadt, and Hecklingen for instance, with which the figures at Cividale may be compared, which are probably of the same century. The influence of Byzantine ivories is evident in the casting of the draperies, an influence which is even more noticeable in the Christ of the fine tympanum of S. Godehard, Hildesheim, of the end of the century. Herr Goldschmidt has published a photograph of this figure side by side with an enlargement of a Byzantine ivory which proves the influence incontestably. This is before the French influence appears, the earliest certain instance of which is in the choir of Magdeburg, where a craftsman who had worked in France commenced working between 1210 and 1220.

Although the most important factor in the making of Romanesque ornament has been proved to be motifs of Oriental origin, modified by local peculiarities and Lombard tradition, the influence of the antique must not be left out of consideration, though its strength varies greatly in different districts. We have seen, for instance, how much the ornament of the south of France was affected by the remains of antiquity still extant there, and at Modena the carving of Wiligelmus on the façade of the cathedral shows classical details in the moulding, and even absolute copies of a winged genius with reversed torch, used as decorative panels; but around Spoleto a school arose in the twelfth century which based its ornament so closely on the imitation of classical details, that the buildings upon which they appear have been held to be entirely antique, though it is only certain portions of them which are so. The door of S. Salvatore in Crocefisso, now the chapel of the cemetery, for instance, and the tympanum of the Temple of Clitumnus, a few miles away, both have the cross interwoven with their ornament in a manner which shows that they are not of Pagan origin—though in each case considerable portions of the building behind are antique and the character of the carving in accordance. The church of S. Pietro, Spoleto, has older reliefs worked into the ornament of its façade with bestiary subjects, but is work of the end of the twelfth century. Yet the patterns carved upon the jambs of the central door are so antique in style, that it is only the perfect fitting of the ornament to the space which it fills which makes it certain that it was carved for its place. An enlarged detail will show this character more clearly. Now it is a very curious fact that this pattern is almost exactly like the jamb of a door of the Syrian second century church of Kanawât, figured in the report of the American Archæological Mission to Syria; and it is strange and inexplicable that two sculptors so far away from each other should hit upon the same treatment of much the same details. Observe also that the rosette patterns of inlay are most of them Oriental. At Narni, the doors of S. Maria Impensole are surrounded by similar ornament which is plainly the work of the same school, the principal of which, the main door of the Cathedral, Spoleto, is signed by Melioranzo, who perhaps was the founder. At Verona too, classical details are frequent. The arcaded cornice of the font in S. Giovanni has among

the heads which serve as corbels a Jupiter Ammon with ram's horns, a Midas with ass's ears, and a head of Zeus. And at Pisa, the pillars at the sides of the central door of the western façade are covered with elaborate arabesques which are so antique in feeling that they too have been claimed as antique fragments though the proportions of the columns are not antique, and the corresponding columns of the door of the baptistery are worked with equally beautiful arabseques, the work of Diotisalvi in 1153, while Guido Bigarelli of Como's font in the centre shows a combination of inlay of coloured marbles mixed with foliage, in which the antique influence is often very visible, though the carving on the lintels is inspired by Byzantine ivories. At the Cathedral of Lucca are other columns with beautiful arabesques based upon classical data, and in the lovely cloister of Monreale, Sicily, one of the most beautiful features is the groups of four colonnettes at each angle carved with similar arabesques.

Again, the scrolls of ornament on the doors of the Cathedral, Zara, are based on classical forms, though indirectly, and they bear great resemblance to those used by Benedetto degli Antelami on the archivolts of the doors of the Baptistery at Parma, and a still closer resemblance to the ornament on the font within. At Borgo San Donino, he used the same kind of details, which themselves are very like the carving directly derived from antique models which we have seen at Arles and S. Gilles, and make it pretty certain the Benedetto had lived and worked in the South of France. Certain details of costume (such as the curious cap, which is also found on a terra cotta dug up at Afrosiab, near Samarcand) and ornament occur in France, and not at all in Italy at any earlier period. His most evident use of the antique is in a figure of a griffin, which is taken almost line for line from a well-known antique, but vivified.

It was probably from the sarcophagi that the arcadings with figures or ornament beneath them, which occur as part of Romanesque decoration, originated. Such compositions as that from the western façade of the cathedral at Modena, in which subjects from the history of Adam and his family fill a series of arched spaces, and form a decoration on either side of the main doorway, are not infrequent. At S. Zeno, Verona, the arched spaces contain a greater variety of subjects, in four rows, each beneath a single arch, ranging from the Creation to the legendary death of Theodoric, with patterns on the bands between, evidently of classical origin; and in the columns of the high altar at S. Mark's, Venice, probably brought from S. Maria in Canneto, Pola, and dating from the fifth century, a whole series of Scripture subjects is treated in this manner, one figure generally tenanting each niche, which makes them rather difficult to comprehend when many figures are required for the expression of the subject. This rather inconvenient method of rendering scriptural and legendary subjects was sometimes used at a later date; the similar pillars at the back of the canopy at San Marco are of the eleventh century, though very inferior in workmanship to those which they imitate; and in the courtyard of the Archbishop's palace at Verona is a column of a later period, as the trefoiled arches show, carved with scrolls with very decorative effect. It was in fact the decorative effect which was sought rather than the effective presentment of the subjects: in such arcadings ornament is often found in place of figures, as in the well-known well-head from S. Samuele, Venice, in which the Byzantine character of the ornament is so pronounced.

There is no doubt that the subjects which the ornamentists used were, to a great extent, symbolical, though enthusiasts have very much exaggerated the amount of intentional symbolism used by the Romanesque, if not by the mediæval architects and designers. Many forms which originally had definite symbolical meaning, with the lapse of years and transference from one country to another, lost that meaning and became merely decorative details, to be used as convenient. A very good example of this is the "hom," the sacred tree of the Assyrians and Persians. This, in the hands of the Byzantines, lost all symbolic meaning, and in European designs derived from Oriental patterns, became merely a decorative detail, as in this window from Santa Maria, Pomposa, in which the griffins are equally without symbolic meaning. Certain Old Testament subjects were often used to symbolise Christian mysteries. The months and their labours, the signs of the zodiac, as at S. Mark's, Venice, at Autun and Vezelay, round the arch, and sometimes heathen personifications are constantly found, and, of course, figures of saints, angels, apostles, and prophets, the symbols of the evangelists, the Agnus Dei, &c. Plants were also used symbolically, of which the one most frequently occurring is naturally the vine. The rivers of Paradise, at which stags fre-

quently are drinking, and the corresponding birds, generally peacocks, drinking from a vase, and the cross of various shapes everywhere. The Psychomachia of Prudentius furnished impersonations of virtues and vices, and the subject of their contest occurs on pavements, and was probably the origin of the popular triumphs of love, chastity, death, &c., at a later period. The bestiaries and early epics were also drawn upon for subjects. Dragons, griffins, and other fabulous monsters occur frequently, and the lion is found with most opposite meanings attached to his appearance. The explanation of these various symbols has been the occasion of much very fine and informing writing; but, while it is possible to make tolerably certain of the general meaning of the symbolism of the ornament upon a building, the fact that many of the details are copied from or suggested by other works, makes it doubtful whether much benefit attaches to the attempt to unravel the symbolism in minute detail. It is much more likely that the craftsman concerned himself merely with the appropriateness of his ornament to place and material than worried himself with its symbolic meaning in the first place; and in smaller works it is still less likely that the symbolism came first, if one may judge by the habits of the craftsman of to-day. In the case of an enthusiast it might be so, but enthusiasts have never been in the majority; in such works as those conceived by S. Bernward and executed either with his own hand or under his direct superintendence, for instance, it is possible that everything may have had a symbolical meaning; for we know that he planned S. Michael's, Hildesheim, with a definite intention, dedicating the building to the Holy Trinity and the Nine Choirs of Angels. It had three naves of three squares, and east and west lay a transept, also of three squares; but I entirely decline to believe that the feeling for symbolism had so permeated the nations of the West as to make it easy for the average public to read obscure symbols, even if it be assumed that the designer used his forms with a definite symbolic meaning. Symbols to be intelligible must be familiar, and therefore trite; a fresh symbolism is necessarily unintelligible, or at least uncertain in meaning. On these capitals from the Cathedral, Autun, are seen the subjects of Androcles and the Lion, S. Hubert or S. Eustace's conversion, the Presentation in the Temple, and Balaam stopped by the Angel. On the other side are the fable of the Stork and the Wolf, the Baptism of Christ, and a Warrior on a Griffin —a very curious mixture, the explanation of which on a definite symbolic plan appears to be difficult.

RADIUM IN THE ROCKS OF THE SIMPLON TUNNEL.*

The principal classes of material which enter into the composition of the massif of the Simplon are: (*a*) The Jura-Trias sediments, lithologically often much alike and much interfolded; (*b*) the Palæozoic crystalline schists; and (*c*) the gneiss of Monte Leone and the Antigorio gneiss, both stated to be of Archæan age. These rocks throughout contain radium, and for the most part in quantities much above what hitherto has been ascribed to sedimentary or igneous rocks.

Some thirty-six typical samples, taken from various points in the tunnel, have been examined. The poorest in radium are certain anhydrite rocks. Certain amphibolite schists go very high. The Antigorio gneiss rises from $10{\cdot}5 \times 10^{-12}$ and $8{\cdot}0 \times 10^{-12}$ grams radium per gram of rock at the Italian entrance to $23{\cdot}7 \times 10^{-12}$ at 4,000 metres inwards. Some of the Archæan gneisses yielded very high results.

Such quantities of radium if generally distributed throughout the rocks of the massif would be sufficient to disturb any forecast of the temperature which under normal conditions would be encountered at the level of the tunnel. It is suggested that the radium was in fact the source of the discrepancy between the predicted and the observed rock temperatures.

As it is improbable that these results are unique and apply only to this particularly sedimentary accumulation and locality, they appear to point to hitherto unsuspected quantities of radium (and its parent elements) in the immediate surface materials of the earth. It seems impossible to avoid the conclusion that these elements were precipitated along with the sediments entering into the composition of the massif. The question then arises whether the accumulation of such quantities of radioactive elements may not enter as a factor in the events attending mountain-building. It can be shown that an area of sedimentation whereon has been accumulated some 10,000 metres of sediments, having a richness in radium comparable with the Simplon rocks, must necessarily become an area of greatly lessened crust-rigidity, and would hence become the probable site of crust-flexure under tangential compressive stress.

Further investigation will be required before such views can be generalised and the importance of

* Abstract of paper read by Professor J. Joly, Sc.D., F.R.S., before Section C of the meeting of the British Association at Leicester.

radium as a source of instability of the earth's crust be determined. Apart from any speculations as to the influence of radium as the cause of an energetic substratum, the shifting of radium and its parent elements by denudation must be regarded as a convection of thermal energy, and this convection, if the quantities involved are sufficient, must, under the conditions referred to above and the unceasing action of denudation, become rhythmic in operation, and at the same time must result in shifting the areas of high temperature and crust-weakness from age to age as the site of sedimentary accumulation changes.

THE TRAINING OF AERONAUTS IN FRANCE.

There is in France, strictly speaking, no school for the training of aeronauts and construction of air-ships in which a definite and prescribed course of study or lectures is pursued. Such instruction and practice in aerostation as are offered are provided by clubs, and by the Government in connection with the military service. There are in Paris four rather important aeronautical societies or ballooning clubs, and five similar organisations elsewhere in France. These clubs were established for the promotion and practice of ballooning as a sport, as well as for scientific study and experiment, and in general for the encouragement of all that pertains to aerostation. In some of these young men are given practical training, taught the theory of construction, and use of balloons, and instructed practically concerning balloon materials and parts, such as the net, anchor, basket, the guide rope, valves, the tying of ropes, knots, &c., the preparation of a balloon for an ascent, and the care and return of the material after descending. Under certain circumstances these pupils—who are always members of the club—may take part in the ascents, learn how to handle the balloon in the air, and descend under different conditions of daylight and weather. If they acquire a certain efficiency in all this, and pass a prescribed examination, they are permitted, when drawn from military service, to enter the "Bataillon d'Aerostiers," or balloon corps of the army. This batallion is established, according to the American Consul-General in Paris, in what is known as the "Menagerie," the old Zoological Garden, formerly belonging to the palace and park at Versailles, and situated between that city and the military school at St. Cyr. Formerly these bataillons d'Aerostiers were distributed throughout the provinces, but since 1870 the Government has concentrated them at the "Menagerie," and they form part of the regiment of engineers garrisoned at Versailles. The post is under the control of a commandant, and the men are taught and practise the handling and care of balloons, of which there are in use several of moderate size, none with a capacity exceeding 900 cubic metres. Besides the balloons, the apparatus and material necessary for inflating them, the equipment includes a plant for making hydrogen gas, which was formerly exclusively used for inflation, but more recently illuminating gas on account of its more moderate cost has been generally employed, especially for free ascents. Most of the ascents made there are with captive balloons. The men who enter this branch of the service are trained at the annual manœuvres for active duty in case of war. Their teaching is practical, and includes all that pertains to preparing, loading, unloading, inflating, deflating, packing up, transporting, &c., but they make no ascents. This is the exclusive duty of officers. Their service lasts ordinarily two years, when they are discharged, subject for call to duty in the military balloon corps in case of war. The main incentive to service at the "Menagerie" is that it offers a less arduous form of duty than ordinary service in the ranks, and, moreover, keeps the young recruit within convenient distance of Paris; but many of the young men have no special gift for the management of a balloon, and opinion among experts is somewhat divided as to whether most of them learn much that would really be useful in the event of actual war.

The second, and far more important institution of this kind in France, is known as the "Etablissement Central du Matériel de l'Aerostation Militaire" at Chalais, Meudon, about midway between Paris and Versailles. It has been in existence nearly a hundred years, and is divided into two general departments, as follows:—1. The arsenal, at present under the command of Commandant Bouttiaux, at which are manufactured balloons and every form of balloon material and equipment for use of the aeronautic service of the French army. 2. The Department of Tests and Experiments, under command of Lieut.-Colonel Bertrand, where new inventions are developed and tests made with gas and every form of material and appliance which pertains to military aeronautics. The institution is in fact a combined arsenal and experimental station, but it is in no proper sense a school, since it has no definite course of instruction, no text-books or specified course of lectures. It is there that the official experiments in aerostation, tests of new materials and original features in construction are made by military experts. It was there that Colonel Renard, twenty-three years ago, built and experimented with "La France," the first dirigible balloon. These two institutions, the "Menagerie" training camp near St. Cyr, and the arsenal at Chalons, are the two principal Government stations for balloon materials in the neighbourhood of Paris. There are besides, several minor depots of such material at military posts near the frontiers, where it would be promptly available in case of war. It is moreover known that two of the French army corps are provided with large dirigible balloons of the Lebaudy type, built for the purpose by the Lebaudy Bros., who also trained at their works the first soldiers who were instructed in inflating and navigating them.

HOME INDUSTRIES.

New Cotton Mills.—Notwithstanding the very general impression that the time is near when there will be much less activity in the cotton trade, and the great number of cotton mills recently erected, the readiness to build new mills continues, as no doubt it will until the period of depression has actually and visibly arrived. But, however anxious speculators may be to build, they are checked by inability of machinists to deliver. Not only is it impossible to induce machine makers to bind themselves to deliver machinery to new mills by a fixed date, they are unable to deliver for existing mills at due date. A partner in one of the largest textile machine making firms in Lancashire has just told an interviewer that his firm have quite recently refused to take an order for six new mills for ring and mule spinning, because "they want to have the wheels going within two years, and it is impossible under present circumstances." It is surprising that there should be any such demand for mills under present circumstances. Not only is the cost of building and furnishing a spinning mill at the present time from 30 to 50 per cent. higher than it was two years ago, unless the precedents of the past are to go for nothing, before new mills can be in working order, any way before they can be running long enough to make anything for shareholders, Lancashire will have to face once more the lean years that hitherto have invariably followed fat ones. Meantime, there are many factories already built, and fitted with engine and gearing, standing idle because preparing and spinning machinery are lacking. The promoters complain that machinery that should now be earning a profit is not even delivered. The machinists guard themselves against actions for damages by refusing to bind themselves to complete orders on any given date. They are very pleasantly placed just now. They are getting very high prices for spinning plant, they are full of orders, and they are under no penalties to complete by any given date.

The Making-Up Trade.—The new Australian tariff is in some respects less favourable to British trade than was hoped. Preference is indeed given to British goods, but it is a preference that may not have much substance in it. The tariff, as might have been assumed, thinks first of Australian industries and how best to protect them. As between the British trade and the foreigner the Commonwealth Government — unquestionably reflecting public opinion—desires to favour the Mother Country, and has done so, but where it becomes a question of a local industry naturally the first consideration is given to that industry, as in the Dominion and elsewhere. Thus the new Australian tariff on wearing apparel is to be 45 per cent., and it is believed among makers-up that the preference in favour of British goods will not prevent the growth of the garment manufacturing industry in large Australian towns. For some time past the shirt, apron, blouse, and allied industries have been developing in Melbourne and Sydney, where they have been actively encouraged by the principal drapery houses, who in some cases run factories of their own. The new tariff is so framed as to encourage the growth of the making-up trades, since while the duty on apparel is high that on cotton and linen piece goods is only 10 per cent. Woollens are taxed higher because in this department of textile production Australian manufacturers have made some little progress. It is believed that the new duties will accelerate the tendency towards an increase of the Australian piece goods trade at the expense of the ready-made business. Already the change is said to have exercised a depressing influence upon garment manufacturers which is the mainstay of many departments of the export trade.

Motor Omnibuses and Speed.—Mr. Thomas Browett writes to suggest the advisability of the Board of Trade insisting that motor-cars shall be fitted with an automatic controller to prevent their running above a maximum speed under any conditions. Mr. Browett recalls that a quarter of a century ago, when steam trams were first introduced into Birkenhead, a firm designed a device said to have been successful for the purpose. There would, he thinks, be no difficulty in fitting a similar device to meet all the required conditions in the case of the motor omnibus such, for instance, as momentary acceleration to enable traffic to be negotiated. It would seem desirable that all motor omnibuses should be required to use some such apparatus to keep them within the limit of twelve miles an hour, a speed quite fast enough for such heavy vehicles on public roads constructed and maintained at the public cost. The omnibuses themselves, as well as the roads and adjoining property are shaken to pieces by the high speeds now common, to the great loss of all concerned. The adoption of such a check would also go far to stop racing for traffic which is now of constant occurrence. The cost of the apparatus should be small, and something would be done to lessen the great loss to private property consequent upon the advent of the motor omnibus. It may be hoped that the authority responsible for London traffic will give early attention to this question of motor omnibus speed, and how best to regulate it. Questioned as to the use of the controller the Home Secretary, in reply to Mr. Harold Cox, said that there is no such contrivance actually in use but that whenever such an apparatus is available the Chief Commissioner of Police will carefully consider the question of requiring it to be fitted to motor omnibuses in the metropolis. It would be interesting to know what has become of Mr. Browett's apparatus.

Old Age Pensions.—The High Court of Foresters, meeting at Leeds last week, came to an important decision. They decided to send forward an instruction to the incoming executive council to submit to the Northampton High Court scales of contributions

for a compulsory superannuation benefit for all future entrants into the society. At present a large number of members receive what is practically an old age pension under the designation of sick pay. Legally, there is only the right to sickness benefit when sick; in practice, the help is often extended to old age. It is now proposed to provide that new entrants be required to pay for a pension at 5s. per week, to commence at the age of 70, in lieu of sick pay. The supporters of the resolution do not desire that the Government should take it as a reason for not pressing on with their scheme of old age pensions. The wish is not to supplant the Government, but to provide the machinery to enable friendly societies to supplement what would come from the Government. Probably, if the pioneers of the Foresters could have foreseen that thousands of old men in the Ancient Order of Foresters would draw pensions from the sick and funeral fund they would have endeavoured to frame their contributions so that the full liability would have been met. "There was no more painful matter," said the Permanent Secretary, "in connection with their Courts than when an old man, unable to work, but yet not suffering from specific sickness, was refused sick pay," and the only way to meet cases of that character "is to set up a pension fund in connection with every Court." It is proposed to pay the pension to the member whether well or ill, and he will not be debarred from working if he so desires. In the opinion of some members the age of 70 is too high, but experience is said to prove that of every 100,000 members who join at eighteen, 33,503 are alive at 70, and the average duration of life after that age is $8\frac{1}{3}$ years. For a pension of 5s. a week at 70, the additional cost at the age of eighteen is 4s. 11d. per annum. Roughly, it may be said that by taking the age 70 of instead of 65 as the pension age the cost is reduced by one-half. It may be noted that the delegates of that large organisation, the Hearts of Oak Benefit Society, also meeting in London last week, passed a resolution that the Board, "whilst trusting the Government will be able to introduce a scheme of old age pensions which will include all persons, fully recognise the difficulty in doing so, and in the first stages of such a great reform, would strongly impress upon them that, through the friendly, labour, and organised registered societies, they would find a large number of persons deserving of State pensions, who, by the fact of having joined societies, prove generally their deserving character, and would respectfully submit to the Government the practicability of founding their scheme firstly through the present organised channels.

The Coal Industry.—The continued rise in the price of coal is a very serious matter for home industries, and probabilities point rather to further increase in prices than to reduction. To the railways of the United Kingdom alone the recent advances in the price of fuel means a prospective additional expenditure of from £1,750,000 to £2,000,000 in the current railway year. And the bearing of the continuous rise in coal prices on the general manufacturing industries of the country is most serious. Miners wages are being advanced all over the country. The Northumberland miners have just been granted another 5d. per day and the Scotch miners are asking for a further advance of $12\frac{1}{2}$ per cent. on the standard, and for a raising of the basis rate of minimum wage from 4s. to 6s. per day. The wages of miners, it must be remembered, are regulated by the coal market. As prices rise so do miners' wages. It is to be noted that the advances in coal have not as yet affected exports, indeed it is the foreign demand for steam coal that is the chief cause of the general advance. Last month 20s. was an extreme price for best Admiralty qualities, but since then there has been an advance to 21s. 6d. to 22s. 6d. The holidays may have had something to do with it by lessening the Welsh output, but there seems to be scarcity in the supplies available for waiting tonnage. The shipments from the Welsh shipping ports this year have exceeded previous records, and there are no signs of abatement in the demand. Some of the Welsh railways have covered themselves in Monmouthshire coals up to May next at advances of 3s. 6d. per ton on expiring contracts. The chief increase in the export demand for Welsh coal has come not from Germany,—the German demand having gone to the North of England and Scotland,—but from France, South America, and Egypt. In the north of England an unprecedented amount of tonnage is said to be waiting for cargoes. Freights are low, and cheap carriage has enabled exporters to secure an abnormal amount of foreign orders for both Northumbrian and Durham coals. In Lancashire the demand for coal is so great that the collieries have had difficulty in meeting it during the holiday season. All over the country the coal markets have been active in what is usually the dull season, and the activity is for home as well as foreign requirements. Then there is the increase in the item of railway charges consequent upon the railway companies ceasing to carry for coal owners $20\frac{1}{2}$ cwt. of coal for one ton. This means a future increase in the railway freightage, and, therefore, of the cost price of coal. The Eight-hour Bill cannot become law this year, but it is quite probable that it will next, and should it do so it can hardly fail to raise the cost of production. Altogether the outlook for the coal consumer has seldom been less favourable, or less likely to improve in the immediate future.

CORRESPONDENCE.

EFFECT OF IRRIGATION ON ALKALI SOILS.

In the discussion upon Mr. L. Robertson's most interesting paper, "Irrigation Colonies in India," an inquiry was made by Mr. H. S. Lawrence on that important point, "What was the effect of irrigation

on alkali soils?" to which very vague and inconclusive answers were given at the meeting. So very vague and inconclusive was the information given, that it seems a suggestion by an outsider may at least afford grounds for some real information being given. All the eminent irrigation engineers who spoke in the discussion agreed that irrigation conferred so great benefits that the effect, whatever it might be on alkali soils, may be disregarded as an argument against irrigation on a large scale. All evaded or avoided answering the question directly. We were told that in the Chenab colony there was no sweet drinking water in the country before the advent of the canal water, and further, that the well in Lyallpur, which was once brackish, had much improved in quality with the flooding of the surrounding lands. We were also told that in Egypt land had been made free of alkali and fit for cultivation by being drowned under three feet of water. These were the only two facts brought up at the meeting, and there being only two mentioned implies a dearth of facts on this important point.

There are so many interesting matters in connection with the inquiry, that I must confine myself to making a suggestion directly answering it. I suggest (1) that the effect of irrigation on alkali soils which have no "pan" near the surface, and below which the subsoil water-level is at a considerable depth, is, by forcing water, which by gravity filters through the soil downwards, to diffuse or disseminate these soluble salts and alkalis through the lower soil and so sweeten the surface soil, which had heretofore, in a dry country, been the recipient of the soluble salts and alkalis left behind by the water drawn up and evaporated during the long periods of drought to which such countries as the Central Punjab and Egypt are subject. (2) The effect of irrigation on soils which have a shallow-seated "pan" is, by bringing on water which always carries soluble salts in small quantity, to add to the total of salts carried by such shallow beds of soil and in time to render them unculturable. To sum up, irrigation can only be beneficial to deep soils with no "pan" and subsoil water at a depth: and it must always in time be detrimental to alkali soils underlain at a shallow depth by a "pan" or subsoil water.

12th July, 1907.

OBITUARY.

EARL OF CLANWILLIAM, G.C.B., K.C.M.G.—Richard James Meade, fourth Earl of Clanwilliam, Admiral of the Fleet, died of pneumonia on the 4th inst., at Badgemore, Henley-on-Thames, after a brief illness. Lord Clanwilliam was born on October 3rd, 1832, and after having received his early education at Eton entered the Navy in November, 1845. In 1854 Lord Gillford (as he then was) became a lieutenant of the *Impérieuse*, and served in her during the whole period of the Russian War. He was severely wounded at the assault on Canton, 1857, became Commander in 1858, Captain 1859, Rear-Admiral 1876, a Lord of the Admiralty 1874-80, succeeded his father as fourth Earl in 1879, became Vice-Admiral 1881, Commander-in-Chief North American and West Indian station 1885-6, Admiral 1886, Commander-in-Chief at Portsmouth 1891-4, Admiral of the Fleet 1895, and retired in 1902. Lord Clanwilliam was elected a member of the Society of Arts in 1891.

GENERAL NOTES.

COTTON AND RUBBER IN UGANDA.—The outlook for these products in the Uganda Protectorate appears to be promising. In his report for the past year, just issued, Mr. Hesketh Bell says that the exports of cotton amounted to about 43 tons only, but nearly 200 tons were purchased from the natives, the result of little more than a year's effort on commercial lines. There seems to be a likel[illegible] culture of cotton becoming a national indu[illegible]. The earlier methods of cultivation were crude [illegible] imperfect. American upland cotton is the most [illegible] genial to the climate and country, and the natives are beginning to grow it extensively. Egyptian Abasic cotton also thrives, though to a lesser extent, and samples of both kinds sent have brought 7½d. and 7d. per lb. As to rubber, tests are going forward. Mr. Bell says that a Para rubber tree, 4½ years old, is 27½ feet high, with a girth of 12½ inches four feet from the ground. About 200 trees, 2¼ years old, grown from seed, are 17 feet high more or less. There has been considerable commercial activity with regard to the product, and ventures on a large scale are said to be pending.

RAISING OF GALVESTON.—Reference was made in these notes last year to Mr. Consul Nugent's remarks upon the level raising of Galveston, and he refers to the matter again in his report just issued (Cd. 3283). As regards the town proper he says good progress has been made since he reported a year ago with the work of raising the level of Galveston protected by and in proximity to the sea-wall. The total quantity of sand filling called for by the contract for the town is 10,470,000 cubic yards, whilst the filling to be done in addition by private-owners brings the total amount up to some 14,000,000 cubic yards. This covers some 426 city blocks, and necessitates the raising from three to ten feet of approximately 2,500 buildings, ranging from small wooden cottages up to brick and stone churches. It is estimated that it will require about two years longer to bring the work to completion. The method employed for the filling by the contractors is to use a canal excavated on the land side of the sea-wall, by means of which dredges containing sand from the bottom of Galveston Bay are enabled to discharge their contents through pipes extending to the portion of the town to be raised.

Journal of the Society of Arts.

No. 2,857. VOL. LV.

FRIDAY, AUGUST 23, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

FOTHERGILL PRIZE.

FOR LIFE-SAVING APPARATUS FOR USE IN NOXIOUS ATMOSPHERES.

The Council of the Society of Arts are prepared to award, under the Fothergill Trust, a Gold Medal, or a prize of £20, for the best portable apparatus or appliance for enabling men to undertake rescue work in mines or other places where the air is noxious.

It is intended that the apparatus sent in shall be submitted to practical trials and tests.

In the award of the Medal regard will be had, firstly, to excellence of design and contrivance, and, secondly, to excellence of manufacture. Credit will be given to such parts of the apparatus as are the invention of the exhibitor; the object being to distinguish the apparatus which gives the best promise of being practically useful.

Inventors intending to compete should send in a notice of their intention, together with a full description of their inventions, not later than 31st March, 1908, to the Secretary of the Society of Arts, John-street, Adelphi, London, W.C.; and in cases in which the apparatus has been put into actual use, the experience of such use should be given, and the special points of merit of the apparatus indicated.

Notice of the place to which the apparatus is to be sent will be subsequently given to those competitors whose apparatus the judges may desire to test, together with an indication of the tests, and of the manner in which they will be conducted.

Competitors intending to patent their inventions should be careful to obtain protection, as the Council of the Society cannot undertake any responsibility as regards the secrecy of the whole, or of any part, of an invention submitted to them.

The Prize will be awarded on the report of judges appointed by the Council.

The competition is not limited to British subjects.

The Council reserve to themselves the right of withholding the Prize, of extending the time for sending in, or of awarding a smaller Prize or smaller Prizes.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

ROMANESQUE ORNAMENT.

BY F. HAMILTON JACKSON, R.B.A.

Vice-President of the Society of Decorative Designers

Lecture III.—Delivered March 11, 1907.

I have observed that in matters archæological the view which a writer will take upon the origin of any forms or artistic tendencies may generally be divined by noting his nationality. If it be a Frenchman who is writing he will find French influence everywhere, the German sees German turns of expression in places where others are blind to them, while the Italian discovers the origin of the most diverse forms of expression in the genius of his nation. It is with some amusement that I find myself treading the accustomed path, and recognising that at the commencement of the mediæval period the English were so far in advance of other nations in the matter of ornament as to make it probable that English influence was one of the great factors in the genesis of my subject. In Northumbria, which Prof. Maitland said was for a while a centre of light not for England only but for the world, and Cumbria, there are important remains of carving of considerably earlier date than the Norman invasion, but in nearly every county

in Great Britain some piece of ornament of pre-Norman date has been discovered. The fragments in the cathedral library at Durham are nearly all Anglian, and may be due to Englishmen working with the Italians who were brought to Northumbria in the latter part of the seventh century, or to the Italians

FIG. 16.

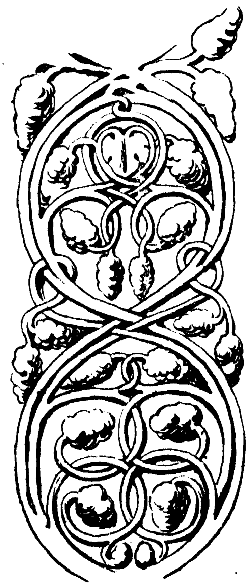
themselves in the cases of the most accomplished pieces of carving. In the celebrated Bewcastle cross, which Dr. Stephens dated 670 from the runes upon it, the knowledge of the figure is very superior to other work of the same time, and points to a foreign workman, as does the repoussé pattern upon the Ormside

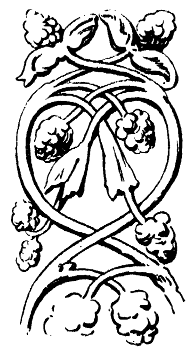
FIG. 17.



PATTERN FROM BEWCASTLE CROSS.

cup (Fig. 16) in the museum at York, the inner bowl of which is decorated with Anglian interlacing work, bosses, and precious stones. The scroll-work upon the Bewcastle cross (Fig. 17), the similar cross at Ruthwell, and the Acca cross, of which fragments are in the library at Durham, is based upon a conventionalisation of the vine, with many interlacing stems and a strong classic feeling in the foliage. At Palmyra, upon the jamb of a door is an elaborately knotted vine pattern, with two bunches of grapes hanging in the middle and two leaves breaking the main curve above them, which reminds one of the Anglian crosses, but shows more license of curve. Acca was Bishop of Hexham after Euta, who succeeded Wilfrid; he died in 740, and the chronicle says that "exquisitely carved crosses were erected at the head and foot of his grave (Fig. 18). The evidence with regard to dates suggests that the Northumbrian crosses (upon which panels of interlacings also occur) preceded those in Ireland, and it has been held

FIG. 18.



PATTERN FROM ACCA CROSS, LIBRARY, DURHAM.

that the interlacing patterns were learnt from Lombardy, which seems likely enough, seeing that we know Italian workmen had been in England. It was in Lombardy that they were used early in the seventh century, as, for instance, upon the pectoral crosses which have been found upon the Lombard graves, upon a cross in S. Giuliano de Budrio, near Bologna, and many similar carved crosses; while the use of such details as the Triskele, which is so frequently found on the Anglian crosses in conjunction with other interwoven patterns, lingers, as on the covers of a Gospel book at Vercelli, which has the name Berengarius upon it, and is probably of the tenth century, but has scrolls in the border, which show forms developing towards the typical twelfth century arabesques.

There are no Irish MSS., metal-work, or ornamented gravestones which can be safely and certainly dated earlier than 700. On the other hand, the Lindisfarne Gospels, the most ancient illuminated MS. with a really reliable date in which the

so-called Celtic ornament appears, has miniatures in which the hair of the figures is curled in the Byzantine mode, while the names of the Evangelists are in Greek, with a few errors, and among the diaper patterns is one like the Roman geometrically pierced transennæ. It bears an inscription in an English tenth century hand at the end of the Gospel of St. John, which gives the names of the makers of the volume, Eadfrith, Ethelwold, Billfrith, and Aldred, all Saxon names. Eadfrith, who was the scribe, was

FIG. 19.

ORNAMENT FROM SAXON MS., CORPUS CHRISTI, CAMBRIDGE.

Bishop of Lindisfarne between 698 and 721; Ethelwold, who bound the book, was bishop from 724 to 740. There is no sign of immaturity in the work; everything is delicately, decidedly, and beautifully drawn, especially the heads of the zoomorphs. S. Wilfrid employed Italian masons to build his church at Hexham, which was elaborate in design and decorated with painting and sculpture, and Benedict Biscop brought workmen from Gaul. Together with the foreigners, Theodore of Tarsus and Adrian, they were at this time busy introducing new rites and fashions, and establishing in the religious houses of the Anglo-Saxon Church a taste for art and literature. The Northumbrian Church gave up the Celtic customs as to the celebration of Easter, the tonsure, &c., in 664, and conformed to the Roman usage, the result of which was,

FIG. 20.

that the Scots Bishop of Lindisfarne, with his monks, shook the dust of England from the soles of his feet and returned to Iona rather than accept what he thought to be rules inconsistent with the Church of the Apostles and mere innovations of the Bishops of Rome. The new churches were of stone, "in the Roman style," in contrast to the plain timber

FIG. 21.

ENLARGED DETAILS OF THE SAME.

fabrics built on Scottish models, and were adorned with sculptures and paintings, which were sometimes imported from Rome, as Bede says, in his life of Eddius. MSS. were also brought, specially by Benedict Biscop and Acca, who erected a "most noble library."

A MS. of Bede's life of St. Cuthbert in the Parker Collection of Corpus Christi, Cambridge (Figs. 19, 20, and 21), has borders which are almost Renaissance in design, so plainly are they based upon classical

models. It is proved to be of the tenth century by the list of archbishops at the end, which terminates with Wulfhelm, who died in 923, as far as the original entries are concerned. Another hand continues the list from Odo, and Archbishop Parker completes it to his own time. The miniature which the borders surround represents a king making an offering to S. Cuthbert, who stands in front of a church; the same colours are used in both. It is believed that it is this kind of work for which the north of England was celebrated in the time of Alcuin (741-80). The "capitula" in the Lindisfarne book contain particulars which refer specially to Naples, and which prove the presence of a South Italian MS. in the library at the time it was written, probably brought by Adrian, abbot of Nisida, near Pozzuoli, who accompanied the Greek Theodore in his mission to Britain in 668. Bede says they went to Lindisfarne. On the carved fragments at Durham the divergent spiral, so characteristic of Irish work, does not appear, while a fragment from Hexham has the "caulicoli" which are common in eighth and ninth century work, as in the bishop's seat at Grado, now on the screen.

FIG. 22.

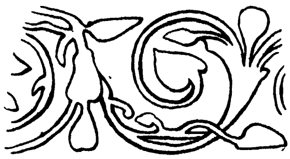
FIG. 23.



ORNAMENT FROM BRITFORD CHURCH, NEAR SALISBURY.

I have put together a few examples which prove conclusively that the Anglian work was based upon Italian data. These include ornaments from the patera of the third century found at Pyrmont (Fig. 22), a piece of carving from Britford church, near Salisbury (Fig. 23), a panel from an Anglian cross at Nunny Kirk (Fig. 24) which has Hexham patterns at the front of it, with birds and beasts facing each other within the scrolls, fragments from Lancaster and Kendal, ornament upon a vase of the Esquiline treasure (Fig. 25), silver-work with a strong Syrian or Alexandrian flavour (Fig. 26), which is of the fourth or fifth century, and a piece of Samian ware found at Buxton

FIG. 24.

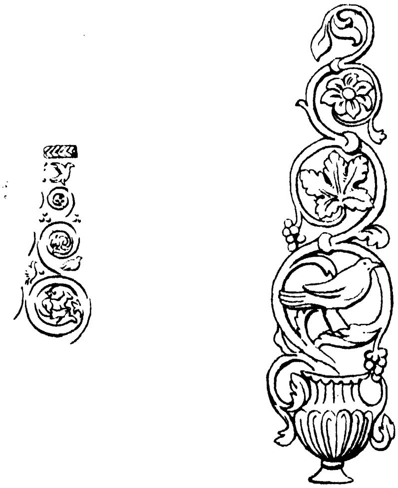
(Fig. 27), with a pattern apparently inspired by metal work.

At Barnack is a pierced window slab, similar to a wooden mid-wall slab which was found in 1869 at Birstall, near Leicester, which bears such likeness in its pattern to others of the

same period scattered up and down Europe, as to render it in the highest degree probable that the various workmen or designers were connected by some bond. You will see on this diagram and the next one three types of pattern (Figs. 28 and 28*a*), one based upon lines cutting at right angles, one upon a mixture of curves and straight lines, and one upon curves solely. In Spain, at Kairouan, in Istria, we find patterns which might come from the same building. In Apulia, in Istria, and England, in Jerusalem, Venice, and Kairouan again, other forms occur with the closest relation to each other, and the step from the freer examples to the beautiful panels from the tomb

FIG. 26.



ORNAMENT FROM VASES IN THE ESQUILINE TREASURE.

of the dogaressa Michieli, in the atrium of S. Mark's, Venice, is a very short one. For the earlier forms at least we may find the requisite connection for the greater portion of the places in the Guild or Society of Craftsmen, called in the laws of the Lombard king Rotharic, "Magistri Comacini." They were largely recruited from the natives of the mountainous district in which the Italian lakes are situated, and in Como itself tolerably early examples of their work may be seen. The jambs of the east door of S. Fedele appear to be fragments of an earlier building, and ninth century patterns are worked into the eleventh century basilica of S. Abbondio. Como was in the patriarchate of Aquileia, and in the cathedral of that city are some very fine slabs of the eighth and ninth centuries. The patriarchs fled to Cividale when the Hungarians came ravaging into Italy, and here, too, are remains of the work of the Comacines. The original font made for Calixtus in the eighth century, though much altered (for it was intended for total immersion) is preserved in the cathedral. In the spandrils are figures of birds and other creatures, rudimentary plant forms appear with rosettes and other Oriental features, which show that the process of welding together diverse influences had commenced. The Croatian *bani* made pilgrimages to Cividale in the ninth century, and took Comacines back with them (as being the best ornamentists to be found, one may suppose), and thus the style spread down the eastern coast of the Adriatic. These panels, now in the museum of S. Donato, Zara, show how closely the style of the different works corresponded, wherever they were executed. At Ravenna one finds the same kind of patterns carved at this period, and sometimes with great delicacy and beauty, as in the canopy of the altar of St. Eleucadius in S. Apollinare in Classe. The convention

FIG. 27.

PATTERN ON SAMIAN WARE FOUND AT BUXTON.

for the bunch of grapes used here occurs over a very wide district and is met with in Visigothic carvings in the middle of Spain. These patterns are found further south on the Italian coast, while from Milan and Pavia, which was a Lombard centre, they spread to Toscanella, Viterbo, the frontier town of the Lombards towards Rome, to Rome itself, and further south along the western coast of Italy. Their occurrence at Toulouse suggests that they spread with the spread of the Visigothic kingdom, or rather perhaps the germs from which they developed. About 418 Honorius ceded the Gaulish provinces to them, and a little later six Visigothic kings reigned in Toulouse, the capital of Aquitaine, during the period of a century. Their kingdom stretched from the Loire to the Pyrenees, and from the ocean to the Mediterranean and the borders of Burgundy, while a great part of Spain was ruled by kings of the same race. The Court was cultivated to a considerable extent, and there was no lack of riches, as is proved by the spoil which Childebert took in 531, when he conquered Amalarik under the walls of Narbonne, his capital at the time. He took 60 chalices, 15 patens, and 20 Gospel

cases, all of gold and precious stones, which he gave to various churches and basilicas. In Aquitaine the Goths were mixed with the Gallo-Romans in an appreciable quantity, as is shown by the place names, and the Merovingian cemeteries show an art with mixed influences, Syrian and Germanic.

There can be no doubt that the Lombards, as the Comacine masters were called after a time, most of them coming from that district, had great influence upon the development of architecture and ornamental art in the eleventh century. S. William, who was born at Novara in 961, according to one account, though another makes his birthplace the island of S. Giulio in the lake of Orta, was a disciple of S. Maieul at Cluny, and elected Abbot of S. Benigne, Dijon, in 990. He journeyed to Rome in 996, and brought back with him nine Italian monks "who were insructed in all arts, which they exercised and taught." In 1001 he began to build the new church, and the sub-structures attest evident connection between the Burgundian school and that of Lombardy, as do other Romanesque constructions in the country. He went on from Dijon to Normandy, to the abbey of Bernay, which he built, and then to Falaise, dying at Feçamp in 1031. Quicherat says that the lower part of the nave of La Madeleine, Vézélay, was built under his superintendence about 1010, and Jumièges and S. Bênoit-sur-Loire were under his influence at their commencement. Jumièges was contemporary with S. Miniato, Florence; it was roofed in the same way with alternate arches thrown across the nave, and roof principals, as was Cerisy-le-Forêt and S. Georges Boscherville.

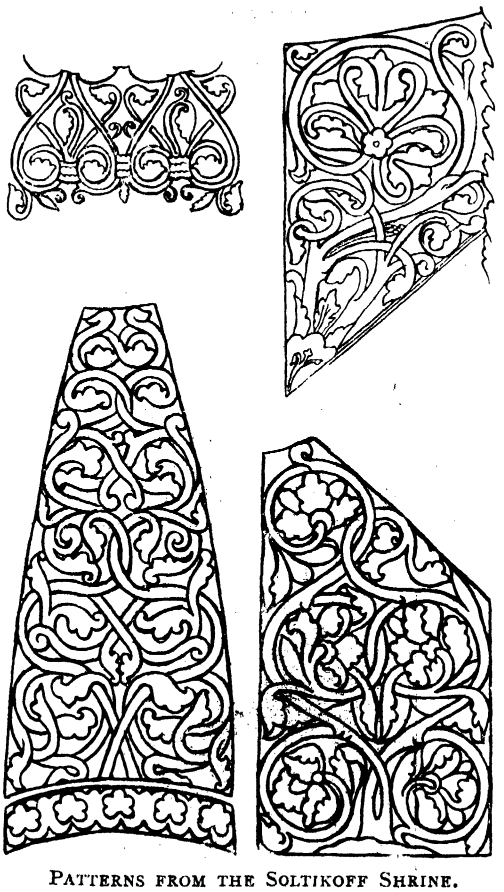
Lanfranc, who was one of the most illustrious and influential prelates in France and England, and one of the greatest builders at the beginning of the Romanesque period, was born at Pavia in 1005, was professor at Bologna before he came to Avranches to teach, and in 1042 became monk in the abbey of Bec, which he made so celebrated. In 1044 he was made Prior, and in 1077 consecrated the church. In 1050 he rebuilt the abbey of S. Evroult, and in 1063 was named Abbot of S. Etienne, Caen, which accounts for the plan upon which it is built. When Archbishop of Canterbury he built a cathedral, parts of which still remain, and founded the abbey of S. Alban's. His disciples spread his influence—S. Anselm, who was also an Italian, William, abbot of S. Etienne, Caen; Yves, Bishop of Chartres; Gondulf, Bishop of Rochester; and Pope Alexander II. There were also continual migrations of masons from north Italy.

At the churches of Nouvion-le-Vineux and Urcel, in the diocese of Soissons, of the eleventh and twelfth centuries, there are caps with lions facing each other, and the well-known Lombard two-tailed syren, closely resembling others at Sant' Ambrogio, Milan, and S. Michele, Pavia; and at Croissy, in Picardy, the twelfth century church has caps with a convention of palm leaves found on the much earlier ciborium at S. Giorgio, Valpolicella, and others which have the form, slightly modified, of leaves on little caps of the sixth century at Parenzo.

In Germany, too, the frequent use of small arcades upon the apses and other portions of churches, points to an Italian influence as well as the entasis, often exaggerated, of the colonnettes whether decorated with carving or plain as in the palace of Barbarossa at Gelnhausen. Charlemagne employed both Italians and Greeks for his church at Aachen, though the actual designer of the building appears to have been a German; in the middle of the sixth century Rufus, Bishop of Turin, sent to Niza, Bishop of Trèves, Italian artists for whom he had been asked, and at a later date also Italians were as certainly brought in as the Byzantines employed by Theophano. Otho III. made a certain Johannes, who is called by the chronicler the best artist in Italy, his painter in the cathedral at Aachen, and commended him to the care of Archbishop Notger, of Liège, and Archbishop Adalbert, of Bremen, had a painter named Trasmundus in his service in the second half of the eleventh century. After Otho I. took the imperial crown he was no longer a German prince; he had an Italian wife and for his son he obtained the daughter of a Byzantine emperor. There was a general enthusiasm for classical studies. Otho's brother, Bruno, Archbishop of Cologne, carried a library with him on his journeys. Hedwig, his niece, could speak Greek, and Gerberga, another relation, was a pupil of the nun Roswitha, who wrote spiritual dramas in imitation of Terence! These studies were not merely the fashion of the court: they were so well taught in the cloister that in the eleventh century the German monks were more learned than those of other continental countries. The revival of culture centred in Saxony and the Rhenish provinces. The royal families made them their favourite residences, and the presence of the court continually increased their population; there, too, were the richest monasteries and

abbeys. Under Otho II. studios were established at Trèves, the imperial residence, under the direction of Bishop Egbert (977-92) and S. Bernward, afterwards Bishop of Hildesheim (992-1022). A little later Siegburg is believed to have been the main centre for enamel work, with which the cloister workshops of Cologne, Verdun, Hildesheim, &c., were connected, though Von Falke thinks that pieces ascribed to its workshops were made elsewhere.

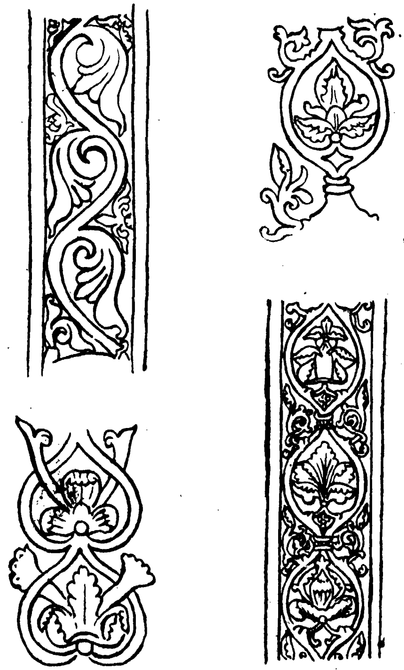
FIG. 29.



PATTERNS FROM THE SOLTIKOFF SHRINE.

At the end of the twelfth and beginning of the thirteenth century some extraordinarily fine metal work was done in France and Germany especially, but also in England, where the Gloucester candlestick, made for Abbot Peter between 1104 and 1113, on a smaller scale anticipates the beauties of the fine fragment at Reims and the splendid Trivulzi candelabrum in the cathedral of Milan. The magnificent shrines at Aachen, Cologne, Maestricht, and other places on the Rhine and Meuse indicate great wealth and remarkable talent among the goldsmiths of the end of the century. The craftsman monk who wrote the treatise "De diversarum artium Schedula," under the name of Theophilus, has been identified by Herr v. Falke as Frater Rogkerus, who was living and working at Helmershausen, about 1100. Several of his works are still extant, and show him to have been a clever goldsmith, who made no use of enamel, but preferred niello. His writings were based not only on his own experience, but upon receipts which he had obtained from Byzantine sources, and in the Lucca MS. also

FIG. 30.



PATTERNS FROM THE ESSEN CROSSES.

the Greek terms which are frequently mixed with the Latin phrases indicate that the technical details were for the most part a heritage from Greek sources. About this time the fine reliquary in the Victoria and Albert Museum, once in the Soltikoff collection, was made. It is the work of Frederick of S. Pantaleon, Cologne, who repeated the design on a slightly smaller scale with variations in pattern. This replica is at Vienna. He also probably made the reliquary at Darmstadt, one panel from which is also at Kensington, since the scrolls of the backgrounds are similar to those at Vienna, though not to those of the Soltikoff shrine (Fig. 29). The patterns upon the domical roof are very characteristic; I show

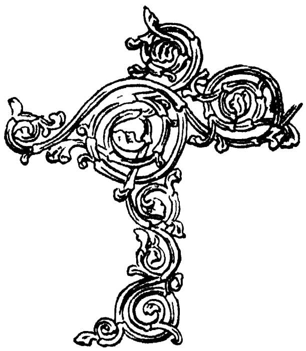
outlines of them traced from Didron's engravings. Abbot Suger of St. Denis (1152) employed several Lorraine artists for two years to make enamel pictures for the abbey. The earliest dated example of champlevé enamel is a cross at Essen (Fig. 30), upon which are the figures of the Abbess Matilda

FIG. 31.

PATTERNS FROM THE ESSEN CANDLESTICK AND TENTH CENTURY ENAMEL.

and Duke Otto, grandson of Otho I., brother of the abbess. He died in 982, so the work must be earlier than that date, but it is so superior in workmanship to another cross in the same treasury that it is suggested that it may be the work of Byzantines. There is another cross, given by Theophano, abbess 1029-54, with Oriental-looking enamels of

FIG. 32.



PATTERN FROM COVER OF GREEK TENTH CENTURY MS. AT SIENA.

birds, griffins, and lions. On the backs of these crosses the patterns are engraved which you have before you, showing characteristic Romanesque forms in a state of development. The Abbess Matilda also gave a fine seven-branched candlestick, of which there is a reproduction in the Victoria and Albert Museum. It was gilded and the knops decorated with crystals and precious stones. Here the Oriental influence is very marked, and the work round the lowest band again shows an approach to the forms of Romanesque while being also a good deal like the border of a tenth century Byzantine enamel (Fig. 31) now at St. Petersburg, both in the tendril-like leaves and the coil of lines. The detail from the cover of a tenth century Greek MS. at Siena (Fig. 32) shows the germs of the design of French ironwork

FIG. 33.

DETAILS FROM GREEK MS. OF NINTH CENTURY.

of the thirteenth century, and the involved curves only require to turn over with interlacing and overlapping a little to be very like those of the twelfth century MSS. written in Flanders. I ought to say, however, that M. Kondakov says that some of the enamels are of the eleventh and even of the twelfth century, but the tenth is the generally accepted period. Other details given from Greek MSS. of the ninth century (Fig. 33) which bear con-

FIG. 34.

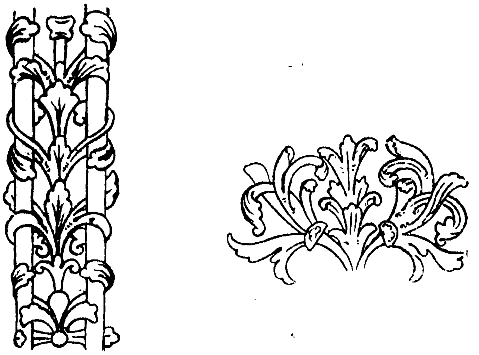
DETAILS FROM NINTH CENTURY CARVING, S. GIOVANNI, NAPLES.

siderable resemblance to portions of twelfth century patterns, can be parallelled by ornament in German champlevé enamels, as in a portable altar at Vienna, in which the flower on the right appears without change. A reliquary cross of the period of Nicephoros Phocas (963-69) preserved in the Franciscan convent at Cortona also has the scroll curves of the twelfth century arabesques fully de-

veloped, but the leaf forms are still rudimentary. Somewhat similar characteristics are found on a piece of carving in the church of S. Giovanni Maggiore, Naples (Fig. 34), which has pierced colonnettes with flowing patterns, and the ground covered with somewhat similar scrolls behind winged beasts. The germ of the twelfth century patterns appears here, with a very decided Oriental influence, which is also evident in some smaller scrolls, with animals in the intervals, which are on the back of a calendar of the ninth century in the same church. The treatment suggests bronze castings chased afterwards, and the details may very probably have been copied from some imported metal object. The derivation seems to be Persian, for some of the beasts are quite Assyrian in character, and the Sassanian carvings which have come down to us show a mixture of Assyrian and Greek influences. The extraordinarily beautiful ornament upon the base of the palace at Mashita, of which the Germans are now the fortunate possessors, is said to be Sassanian. It shows elaborate scrolls with beasts among them or facing each other over vases as in the well-known Byzantine subjects and a naturalistic feeling for detail which reminds one of the beautiful scrolls from the chair of Maximian at Ravenna, which I have shown you, and the ornament upon the great torus moulding suggests twelfth century French work at first sight. A less remarkable example is at Rabbath Amman, in which arcading occurs with zigzag and cable mouldings, with patterns beneath the arches like the Lombard carving of the ninth and tenth centuries, which is considered to be early Saracenic. A bordering strip has a kind of scale pattern of lines upon it which also appears on early mediæval sarcophagi at Trèves and in the south of France. In both these cases Hindu details and modes of work occur, but they are probably due to Syro-Greeks and imitate the design of textiles. Dr. Strzygowski concludes that Mashita is certainly the work of a Mesopotamian architect. If the opportunities for copying had been as great when these buildings were erected and ornamented as they are now, one would say it was needless to look further for the origin of Romanesque ornament. It is curious how long the type of foliage shown in the drawing from S. Giovanni Maggiore was in use. The elaborate scrolls upon the jambs of the west door of the Cathedral, Benevento, have the same kind of growth and much the same terminations, though it was carved in the twelfth century (1150-51), and the cathedral of Modena also has the same kind of scrolls decorating the jamb of the west door.

The revival of learning by Charlemagne brought Irish, Anglo-Saxon, and Carlovingian scribes in contact, and it is generally acknowledged that the term Franco-Saxon is properly descriptive of the MSS. executed in the north of France and the Low Countries in the ninth century, of which the Bibles of Charles the Bald are the best known examples, so that a similar influence from the English scriptoria might be expected in the next century. Now if we examine the MSS. executed at New-minster and isolate the details, we shall find several which are familiar to us at a much

Fig. 35.

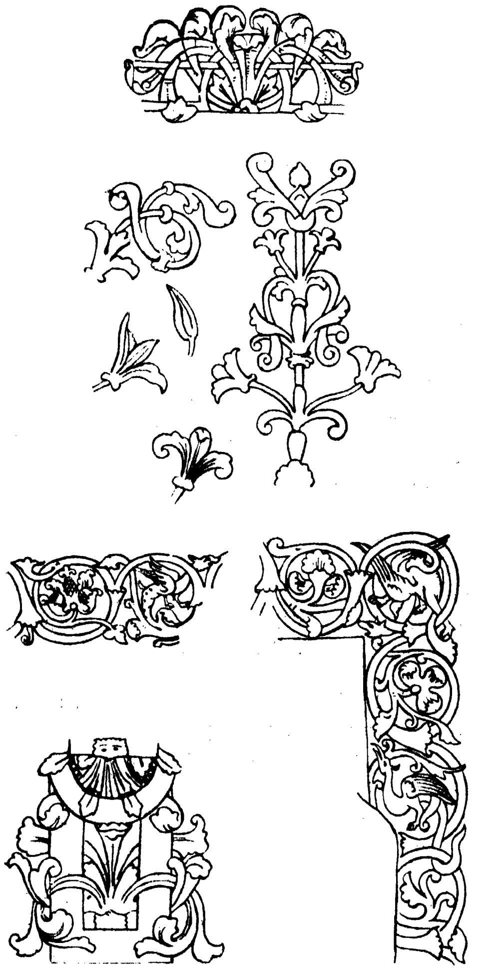


Ornament from Winchester Charter and Tenth Century MS.

later period. This, for instance, I am sure, would not much surprise you in the border of a thirteenth century window, but it is from the charter of 966 (Fig. 35), and these details of a somewhat later date may be paralleled by foliage both carved and wrought in iron many years after on the continent (Fig. 36). The New Minster at Winchester was founded by Alfred and put under the rule of the learned Grimbald for the purpose of educating the sons of the nobles. Grimbald had been in the monastery of S. Bertin in Artois and entertained Alfred there when on a journey to Rome in his youth. In 884 or 885 the King sent an embassy to Fulke, Archbishop of Reims, and the Abbot of S. Bertin, entreating their sanction to his coming. They presented a gift of wolfhounds. Fulke said that he sent in return a spiritual watch-dog to guard the Christian flock. Alfred assigned an eighth of the revenues of his kingdom to its support, and told his nobles either to study or resign

their offices. He said his desire was "to provide houses for study, workshops for the writing and adorning of beautiful MSS., peaceful patterns of civic life, well-ordered communities resonant of labour and praise." A great school of illuminators was developed in the abbey, which produced some of the finest

FIG. 36.



ORNAMENTS FROM ENGLISH MS. OF ELEVENTH CENTURY.

MSS. of the period in existence, among which may be mentioned the Benedictional of S. Ethelwold, written by Godemann, who became abbot of Thorney about 970, and the MS. in the library at Rouen, which is so much like it, and was probably written for the first Benedictine abbot of Glastonbury, Ethelgar (965), who was made Bishop of Selsey in 978 by Dunstan, and succeeded him as Archbishop of Canterbury in 988. Robert the Norman was made Archbishop of Canterbury by Edward the Confessor, but was obliged to fly before the English indignation, and carried this Benedictional with him. In the register of Hyde Abbey (as Newminster was called when it was removed outside the walls) is a fragment of exultet with the musical scale in use

FIG. 37.

B. FROM WINCHESTER TENTH CENTURY MS.

before Guido, of Arezzo, invented the present gamut in 1020. It contains the names of several illuminators, Ælsinus, Æthericus, Wulfricus, all Saxons. It was written for Ælfwine, who was then monk and deacon.

FIG. 38.

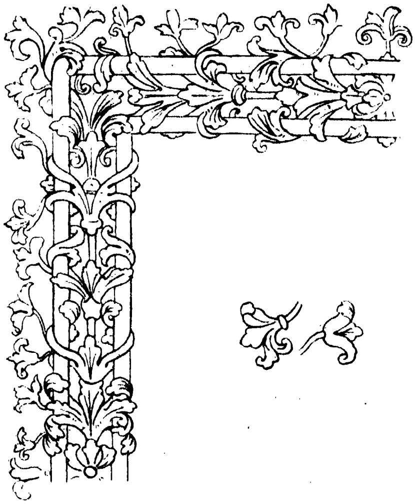
ORNAMENT FROM SAME MS.

He became abbot in 1035. This fine B (Fig. 37) is from a psalter written in 963. It served as a copy for other MSS. written at a later date. The scroll work (Fig. 38) is from the insides of other initials of the same MS., and shows how near the design had come to the fine German twelfth century initials. This is

another piece of the border of the charter of 966 (Fig. 39), and shows the development of details from the earlier Saxon MSS.

In later Saxon times intercourse between England and Germany was close and frequent. As early as the end of the eight century an Englishman named Lul was established at Mainz to whom S. Cuthbert, Abbot of Jarrow, wrote asking him to send experts in glass-making. Carolingian culture had two principal centres, Tours and Aachen. Alcuin, of York, planted in the school of Tours his own Northumbrian learning and had pupils from

FIG. 39.



BORDER OF CHARTER OF 966.

nearly all the centres whence the first feeble struggles of mediæval art proceeded. Dr. Smith says in his dictionary of Christian biography, "Among the scholars in the palatine school were Charles himself with his sons Charles, Pipin and Lewis, his sister Gisela and his daughter of the same name; Angilbert, afterwards Abbot of S. Riquier; Adalhard, Abbot of Corvey; Rigbod, Archbishop of Trèves; Rictrudis, a noble nun of Chelles; and Gundrada, sister to Adalhard. His most famous pupils during his later years at Tours were Rabanus Maurus, afterwards Archbishop of Mainz; Hatto, Abbot of Fulda; Haimo, Bishop of Halberstadt; Samuel, Abbot of Lorsch and afterwards Bishop of Worms; Adalbert, Abbot of Ferrières; Aldric, Bishop of Sens; and Amalanus, deacon of Metz." From the sixth to the eighth century missionaries went from Britain to Frisia, Germany, Switzerland, and even to Italy. The same ornamental motifs are found in Ireland and in Switzerland, where Latin culture was preserved.

In the treasury of the principal church of Maeseyck a MS. of the Gospels is preserved which dates from the eighth century, and has illuminations quite Anglo-Saxon in character, together with fragments of embroideries, similar in design, which were found in a shrine. They are the work of two nuns, sisters, named Erlinde and Relinde, painters and embroiderers, according to tradition, who learnt their craft from Anglo-Saxon missionaries. As late as 1183 Anglo-Saxon design exercised a certain amount of influence. The church of Petit Quévilly, near Rouen, has painted decoration, said by M. Gonse to be of a rich, severe, and delicate style of a curiously Anglo-Saxon character. S. Columba founded monasteries at Fontaine, Anagratum, and Luxeuil, at the end of the sixth century, and then Bobbio in Italy in 613. He also lived near Bregenz. S. Gall, the apostle of Switzerland, whose Irish name was Cellach, went thither, at the beginning of the seventh century, and founded his monastery in 614. S. Cataldo (Cathal), patron saint of Taranto, was a pilgrim Scot from Lismore, in the seventh century. S. Donnat (Donncadh), his brother, was Bishop of Lupice, in Naples. St. Kilian, apostle and martyr of Franconia (689), is commemorated at Würzburg, where the MS. of the Gospels found in his tomb is annually exposed on the altar. At the monastery of Honangia, founded on an island in the Rhine near Strasburg, by Tuban, an Irish bishop, a charter of 810 is preserved which recites grants to the monastery, the poor, and pilgrim Scots. Nine Scots are named in it, eight of them bishops. There was a convent of Scots at Mount S. Victor, near Feldkirch, in the ninth century, and Dungal the Scot, author of the letter to Charlemagne on the eclipses of 810, became preceptor of the cathedral school at Pavia. Willibrord and Boniface, who came from Crediton, sought the conversion of Frisia and of central Germany in the first half of the eighth century, and they were accompanied and followed by a large number of Anglo-Saxon fellow workers, SS. Lievin, Wilfred, Wigbert, Suitbert, Ewald, Willibald, nephew of Boniface, Wynnebald, &c. Willibrord founded Echternach before 739, and Suitbert founded Kaiserswerth. Fergal or Virgilius, an Irishman, was Bishop of Salzburg in the eighth century. The relics of British saints are revered in other Continental places which commemorate their names, as S. Gobain near Laon, where the

relics of S. Gobhan are enshrined above the high altar. In 856 Ethelwulf married Judith, daughter of Charles the Bald ; Ogive, daughter of Edward the Elder, married Charles the Simple; Hedwig, Hugues the great Count of Paris ; Edgiva, Louis the blind Count of Provence ; Adela, Ebles Count of Poitiers Another granddaughter of Alfred wedded Otho the Great of Saxony. At a later period the emperor was married to Chunelinde, daughter of Cnut, the Athelings, Edmund and Edward, had married nieces of the emperor, and German clerks were at the head of the Wessex church —so the channels for reciprocal artistic influence were open between the countries, and continued so, for in 1114 Henry V. of Germany married Matilda, daughter of Henry I. of England, who after his death in 1125, married Geoffrey Plantagenent, Count of Anjou, in 1129. (Figs. 40 and 41). But the plan lines are nearly the same as those from a vase in the Esquiline treasure, which we have seen repeated upon the Anglian crosses at Nunnykirk, Lancaster, and Kendal, and similar curves form the bases of many of the late Roman mosaics of ornament both on vault and floor. In these panels from Torcello we have a modification of the same kind of curves, with foliage flowers in the centre and with animal forms introduced (as they are also in the Esquiline treasure) and animal forms playing through the scrolls are one of the characteristic details of Romanesque ornament. The heart-form as basis for ornament, so frequently used in German Romanesque especially, as in this late example from Gelnhausen, is Oriental, and the strap-like processes which enwrap it are seen in early Saxon MS., while the flower in the centre

FIG. 40.

ORNAMENTS FROM CATHEDRAL, VERONA.

In every pattern there are two portions, the underlying curves or geometrical planning, and the details which disguise or emphasise the basis according to the fancy of the designer. Now the schemes of curvature of most of the Romanesque scrolls are simple, and common to both later classical and Byzantine ornament. In this ivory vase from the British Museum, for instance, which is probably of Syrian manufacture, the curves might be of any period from the sixth century to the tenth, while the birds in the borders suggest Coptic influence, and the antique frets have developed into the riband pattern which we have seen at Moissac and Avalon. The heads in circles seem to be an earlier form of a detail frequent in Byzantine work of the tenth or eleventh cenury. Take next this strip of ornament from the Cathedral, Verona, and compare it with this gold bracelet in the Franks Collection at the British Museum, said to be Egypto-Byzantine work, and the virtual identity of line and subject is apparent. is based upon Byzantine details. The elaborate interlacings of curves in the splendid initials of the German MSS. of the twelfth century are only developements of the same features used at Winchester and elsewhere long before.

FIG. 41.

ORNAMENT FROM BYZANTINE BRACELET FROM EGYPT, BRITISH MUSEUM.

In the Victoria and Albert Museum is a curious little carved oval box which is said to be Byzantine work of the ninth century. If this ascription is correct, about which I have my doubts, though I cannot speak as an expert upon the matter, it is a very curious example of the early evolution of an ornamental form which is of frequent occurrence in the twelfth

century. I mean the scroll flowers on the lid which only require a slight scalloping at the edges to become quite like ornaments which are common in the MSS. of that period illuminated in Flanders and North West Germany.

We have seen that the Comacines or Lombards had a great deal to do with spreading certain patterns round the basin of the Mediterranean, and that Lombards at a later date were the prime movers in the development of the architectural style termed Romanesque. Most of these masters were ecclesiastics of one kind or another, or at least worked under the shelter of the church in which they had taken some kind of vows. The cloister was the only secure refuge for those who were not prepared to make fighting their principal business, and men of refinement who were peaceably disposed naturally gravitated to it. Here men of various nationalities met and could discuss problems which had arisen in following their various pursuits, for all those instructed at all spoke Latin, and learning progressed. Here was the great scriptorium where valuable books were written and illuminated; here were the workshops, in which work in all kinds of materials was carried on; here were the masons, the designers, the carvers, enamellers, goldsmiths, mosaic-workers, painters, writers, joiners, and so forth—a busy hive of constant employment. The country was made to blossom and bear fruit, architectural and engineering works were carried out, and protection was afforded to all the vassals. The great Benedictine monastery, in fact, was the centre of all kinds of mental activity. Take the history of S. Bernward as an instance of the life of such a master. He was born about 960, of a noble Saxon family, and brought by his maternal uncle, Deacon Folkmar, later Bishop of Utrecht, to the Hildesheim cathedral school, which was under the direction of Thangmar, schoolman, notary, librarian, and dean at a later period. At that time the bishop's court of Hildesheim was the centre of culture of Eastphalia, embracing great variety of pursuit and also the practical use of mechanical arts. His biographer mentions that Bernward practised artistic writing, painting, working of metals, setting precious stones, and architecture. Cloister workshops, schools, and warehouses lay upon and around the cathedral hill. He was ordained exorcist, and afterwards priest. He then went to his maternal grandfather, the Pfalzgraf Athalbero, and managed his affairs till he died in 987. He was then summoned to Court, and made tutor to the youthful Otho III. by the Empress Theophano. After her death he was made Bishop of Hildesheim, and consecrated in 993. Thangmar gives us details of his daily occupations. Not only in Hildesheim, but in other places in the diocese he founded scriptoria for the production of liturgical, philosophical, and theological literature. In the workshops painting and sculpture, goldsmith's work, mosaic, and the laying of tiles by a process of his own were carried on. Talented youths accompanied him on his journeys to make drawings of notable things which he had not time to record himself and to study. He planned the church of S. Michael Hildesheim, and most of it was carried out under his superintendence, though the fire of 1186 destroyed a good deal of his work. He made several crosses ornamented with filigree and pearls and with large crystals on the arms, a silver crucifix with the body arranged to hold relics, two gospel book-bindings and a paten with engraved panels of the cardinal virtues. Several MSS. in the treasury were written for him. In the Magdalen church are two candlesticks of an alloy of silver and copper, formerly gilded. His celebrated doors were made for S. Michaels in 1015. He also made a column of bronze 14 feet high with reliefs from the life of Christ in the manner of the Trajan column; and his graveslab and sarcophagus, both of which Thangmar notes as being his own work. Another example is Bishop Benno, of Osnabruck, who practised nearly as many different arts as S. Bernward. He first appears as a pupil, but soon acts as master builder at Hildesheim, then goes to Hungary with a host on account of a famine, finishes the building of castles left incomplete by Henry IV., then acts as viceroy for Archbishop Anno in the principality of Cologne. After he became Bishop of Osnabruck he drained the marshes, and became so celebrated as an hydraulic engineer, that the Emperor called him to Speyer to make the cathedral secure from floods of the Rhine. At a later period he often accompanied him on his journeys (carrying on his building operations by correspondence), and had artists with him to make drawings. Norbert, abbot of Iburg (1118), his biographer, says that when he was building the monastery of Limburg, the cathedral of Speyer, which was finished in 1060, and the collegiate church of S. Guido in the same city, he established a school of architecture

there under the protection of the emperors, and that pupils came from all parts of the empire to give themselves with ardour to the study of architecture.

The activity of these great men is astounding. They combined the practice of the architect, the founder, sculptor, painter, scribe, goldsmith, and even the organ builder, and were also teachers, theologians, and sometimes physicians, statesmen, and jurists. In England also ecclesiastics were often capable craftsmen. Leaving out S. Dunstan as being well-known — "who understood masonry, carpentry, and smith's work; could draw, paint, and design; was a musician, composer, and maker of musical instruments," as well as a distinguished ecclesiastic; let us take Anketil, of S. Albans, who was brought up as a goldsmith, and had passed seven years in Denmark making things for the king and superintending the royal mint. Returning to England, he became a professed brother of S. Alban's, and made the great feretrum, shrines for the relics of SS. Bartholomew, Ignatius, Laurence, and Nigasius, elaborate candlesticks, censers, and incense boats. The shrine of S. Thomas, of Canterbury, was the work of "that incomparable official," Walter of Colchester, sacrist of St. Albans, who was assisted by Elias of Dereham, Canon of Salisbury. Three smiths "expert at shaping" are mentioned by name among the monastic brethren of S. Patrick, and three skilful artificers. A bishop named Coula was S. Bridget's principal artist in gold, silver and other metals. When the same man worked in metal and illuminated MSS it was natural for the patterns to be sometimes counterchanged, and this may perhaps explain the genesis of the involved patterns known as Celtic, which Mr. Romilly Allen says must have been copied by Christian artists from the designs invented by Pagan enamellers upon late Celtic bronze bowls. Since all the bowls of this class have been found in England it is there that the spiral work of the MSS. must have originated and not in Ireland. If this theory is correct it will explain the perfection of design and the certainty of hand in the earliest certainly dated MS. with zoomorphic patterns, the Lindisfarne Gospels—in which the elaborate interlacing patterns appear to be derived from metal work. S. Dageus, who lived in the sixth century, and made many shrines, was also an illuminator. S. Éloi made shrines of gold and silver to many saints, which his biographer enumerates, and was Master of the Mint to three French kings. The annalists of the ninth and tenth centuries mention a number of works of art, including metal work for altars, made by monks. Folcuin, in his life of Notger, Bishop of Liège (971-1008) describes a wonderful Gospel ambo which he had made. "It was composed of a hollow formed of four half-cylinders set crosswise. The four faces of bronze, worked with the hammer, were, according to the fancy of the artist, covered with chisellings and with gilding, and held together by silvered uprights. On the north side the ambo had a reading-desk in the form of a cast eagle magnificently gilded, which raised its wings or extended them to receive the gospel book. The neck moved by means of an ingenious mechanism—the bird appeared, in some way, to listen to the deacon's chant, breathing forth at the same time clouds of perfumes produced by incense thrown upon lighted braziers hidden inside the body." Villars de Honcourt draws such an eagle, and at Mainz there were two cranes which behaved in a similar manner. These mechanical pieces of furniture were probably suggested by the report of the magnificence of the throne called "Solomon's" in the imperial palace at Constantinople; which was of gold enriched with precious gems with mechanical birds which sang perched upon it: "above shone an immense cross encrusted with precious stones; around were golden seats for the imperial family. On the steps were two lions of gold, which rose to their feet, roaring. Thereby were golden trees, on the branches of which birds of different kinds imitated the songs of those in the wild wood."

With craftsmen of such capacity within the monasteries—with men of such varied powers directing affairs—with the contact and friendly competition of the qualities of many nationalities, Eastern and Occidental, meeting in the truly cosmopolitan cloister: and with varied and suggestive material brought to the door by commerce, either the spoil of ancient civilisations or the traditional products of the unchanging East, was formed a cradle in which the young Romanesque art was fostered, and from which it soon leapt forth in strength and splendour to pleasure the West with its beauty.

I have now shown you what Romanesque ornament is, and I hope justified the strong expressions of appreciation of which I made use in the opening lecture. I have demonstrated that it is principally based upon Byzantine design, which itself was based

upon Persian and Syrian ornament, and have given instances in which the direct influence of Oriental models may be assumed; I have traced various modes in which these influences probably penetrated the various countries of the West, and how they were modified by local and national peculiarities, among which I have shown that the English may have borne great part; and, finally, that the principal portion of the welding together of the various elements of which the style is composed took place in the cloisters, where art work of many kinds was carried on side by side, each craftsman influencing his neighbour whether working at the same or at a different craft. And it now only remains for me to express my thanks, firstly to you for the patience with which you have borne with my transgressions of the hour limit, which appears to be considered the measure of the endurance of an English audience; then to the authorities at South Kensington for their kindness in preparing slides of 15 subjects from the Museum; and, finally, to my friend Mr. Ashton, whose admirable management of the lantern has allowed you to see the fine collection of slides made from his excellent negatives to the best possible advantage.

INTERNATIONAL CONGRESS OF SCHOOL HYGIENE.

The President and Hon. Secretaries of the Second International Congress on School Hygiene have communicated the following account of the arrangements for a new permanent council which were resolved upon at the closing meeting of the Congress:—

The permanent International Committee, consisting of about sixty members, selected from almost every country, has hitherto only met during congresses. Arising out of the question of whether it would not be a proper thing to establish a bureau, with a permanent staff, library, and museum, and so on, in some central but neutral spot, such as a Swiss or Dutch town, it was decided, as explained by Drs. Mathieu, Burgerstein, and Kerr, that it would probably lead to greater progress if such bureau was not localised, but if each country had its own centre for the diffusion of knowledge, and to act as a clearing-house in the matter of school hygiene statistics, laws, and regulations. Finally, to supervise in scientific matters, and generally to do all that is possible at all times or places to forward the human interests which are bound up in the special lines of knowledge included in school hygiene, the International Committee has formed a small council.

This Council has all the powers of an ordinary committee. It can form sub-committees of experts on special enquiries. The usual committee procedure is to sit round a table and discuss matters, but this Council will deal with the various subjects that arise, submitting the different topics by correspondence, collating the answers, and, finally, making pronouncements in urgent matters after a meeting of the Council.

It is obvious that for efficiency such Council should be small and yet have in it elements to secure permanence, and, at the same time, possibilities of slow but constant change. This has been done by deciding that it shall consist of the president of the past Congress, the president of the Congress which has just been held, and the president of the next Congress. Nine other members are to be elected, of whom three are to be from the country where the Congress was last held, and three from the country where it will be held next, three being selected from other lands.

Certain matters, for instance, will almost at once come under the consideration of this Council. Such might be quoted as:—

"The question of how medical inspection of schools can best be carried out with the maximum of efficiency and minimum of cost.

"The question of how far the laws of health can best be imparted to the coming generation so that later they will know how to care for themselves and those dependent on them.

"The best systems or methods of physical training for both sexes at various ages.

"The feeding of children requiring proper nutrition so that it shall be done without developing pauperism, and with regard to those upon whom the cost falls."

These four matters are being dealt with practically in a great variety of ways, and this Council should be able to collect and analyse known facts to show which methods are best for any town or State.

It is obvious that information thus digested will have a very great value politically as well as educationally, and this Council may in time come to be officially regarded as quite analogous in matters of school hygiene to that other Congress of Peace now in session at the Hague.

RISE AND TENDENCIES OF GERMAN TRANSATLANTIC ENTERPRISE.*

There was no German traffic beyond the seas to speak of before the formation of the United States. The consequent disruption of the Colonial system produced lively trade-relations during the ensuing period of French revolutionary wars. After a short interruption, produced by the "continental system" a second impetus was given by the establishment of other independent States in South and Central

* Abstract of paper read by Professor Ernst von Halle, Ph.D., before Section F of the meeting of the British Association, at Leicester.

America, 1815-1830. The abolition of the Colonial system in the rest of the European colonies marks the third phase of expansion, and the opening of trade relations with Eastern Asia; commercial treaties with Japan and China the fourth. Preceding the formation of the German Empire there existed a very limited commerce with Africa. By 1871 German tradesmen and bankers, particularly sons of the Hanseatic towns, were to be found in all parts of the world.

A few German merchant princes, and a larger number of small tradesmen abroad, not only maintained relations with their country, but also handled the traffic of other commercial nations.

London was the money market, and to some extent the money lender. On the other hand, a large share of German Transatlantic exports and imports passed through English warehouses, and more still in English bottoms. The political decentralisation of the country had for centuries left the majority of German States without seaports and seafaring interests. The Zollverein brought commercial unity to the interior and Baltic sections, but did not embrace the North Sea ports till after the three wars which gave the Empire a flag and a commercial policy.

At this time the population, which had doubled since 1800, numbered 42,000,000. In the next thirty years 20,000,000 more were added; 65,000,000 live to-day where about 20,000,000 lived at the close of the Napoleonic wars. Besides the increasing population, three events—the opening of the grain fields in North America, the introduction of iron and steel steamers into the Transatlantic freight service, and the rise of large industries in Germany after the war—were the chief cause of the country's transition from a grain-exporting nation into a grain-importing nation by the middle of the seventies. The industrial crisis increased the protectionist tendencies among the manufacturers, while American competition turned the agriculturists to protectionism. But the new economic policy did not stand in the way of rapidly increasing imports, which had to be paid for by increasing exports.

It was not the manufacturing interests that nourished exports, but rather the demand of a growing population for food-supplies and industrial opportunities of employment. Up to this time Transatlantic enterprise had been of a somewhat incidental significance for German national economic life: it now became vital. Larger exports of merchandise and capital for foreign investment, the establishment of large commercial fleets, insurance and cable companies, now became necessary to meet the increasing requirements of the importing interests. By inaugurating a Colonial policy in 1884 Bismarck meant to crown the process of empire-making.

The censuses of 1882 and 1895 show a remarkable transformation in the economic structure of Germany. Unable to employ a larger number of people in its pursuits, agriculture had thrown the full surplus population into industrial occupations. The agricultural classes in 1815 numbered about 18,000,000 about the same as a hundred years ago, whilst the industrial population had increased 600 per cent. The standard of life had improved throughout, chiefly in the middle and lower classes; but in spite of the introduction of scientific methods, agriculture was unable to keep pace with requirements.

By 1900, one-fifth to one-fourth of the foodstuffs, and more than nine-tenths of the raw material for clothing had to be imported. Had not a rapid development of foreign trade and rising foreign investments closely followed the resulting neccessities, either starvation, or emigration, or foreign war would have resulted.

To avoid a precipitated industrialisation and a dangerous decline of agriculture, the country decided upon an increase of agricultural protection. Germany's geographical position will always necessitate an ample agricultural resource at home to avoid the dangers of starvation in war times. It was compelled to sacrifice some of the industrial possibilities of tariff-treaties to this point of view.

The situation to-day is that Germany's foreign commerce amounts to £750,000,000, of which £425,000.000 are imports.

Of the difference, fifteen to twenty millions are made up in the earnings of German shipping, the rest in the interest from foreign investment, consisting of £450,000,000 investments in trans-oceanic countries, £800,000,000 foreign stocks and bonds (of which more than £100,000,000 is trans-oceanic), and more than £250,000,000 other investments.

Of the imports, about 40 per cent. come from over the sea outside of Europe, while of the exports a little less than 25 per cent. go to foreign continents, more than 30 per cent. of its trade.

With neighbouring countries Germany exchanges more than 40 per cent.

The trade with the United Kingdom amount to about 20 per cent. of exportation and 14 per cent. of the importation, and with the British Empire 24 per cent. of exportation and 22 per cent. of importation. While England has ceased to be paramount in German Transatlantic trade, it still holds the first rank. Of the commerce of the world, incoming and outgoing, the three leading countries—England, Germany, and the United States—to-day control not less than 40 per cent. in either direction. Of this, a large share is transacted among these three countries.

German exports have not increased as rapidly as the demand for imports. The foreign investments are rising in importance. They may become the leading feature by the time that machine-using industries have become more extended in tropical and sub-tropical countries. Germany will have to improve its commercial and industrial processes, its means of transportation, and its business organisation to keep pace with foreign competition. The real dangers of the competition of the future are neither to be found in England nor in Germany, nor even in the United

States, though this latter country makes a more rapid progress than the two former. They will ensue from the working of certain natural laws: increasing populations, increasing demand for the products subject to diminishing returns, and increasing supplies of the products subject to increasing returns.

The political tasks of Germany's future are continental, in consequence of its central position, but her economic tasks will necessarily consist of an extension of every form of her commercial sea-interests.

THE MOTOR CAR TRADE IN THE FAR EAST.

In Singapore, the Federated Malay States, and in the islands of Sumatra, Java and Borneo, the motor-car trade is yet in its infancy. In Singapore there are at present about sixty passenger cars, and some fifteen to twenty goods-carrying lorries. In the city of Singapore the cars are all owned by doctors, professional men, and some motor enthusiasts, and the interest in motors is said to be growing daily. According to the American Consul-General, the field being practically uncanvassed for many years, it has not been thoroughly gone over, nor have the majority of the right people been approached for the sale of motor-cars. The roads are excellent, being entirely macadamized, and are constantly cared for by the Government; in some portions of the city the gradients run from 20 to 30, and in no instance are the roads less than sixty feet wide. To obtain a license to drive a motor-car or a motor-cycle, one must apply and pass an examination before the chief of police, and if in his estimation, the candidate is capable of handling a car the license is granted on payment of a fee of about two shillings and fourpence. Apart from Singapore the demand for motor-cars is growing extensively in the Federated Malay States, and in Sumatra and other islands in the vicinity. The Chinese and natives take to motoring very easily, their chief interest being centered in the decorations and colour of the body of the car rather than in the ability or workmanship of the engine. Of course it is needless to comment upon the tastes of Europeans, there being a sort of national pride on the part of the English and French to drive nothing but their own manufactured cars. The greatest difficulty is the constant heat, as this causes tyre troubles, and while the majority of cars are equipped with pneumatic tyres they are now putting on clincher tyres, taking the risk of injury to the engine and car in preference to the constant purchasing of new tyres. The favourite car is a four-seated ten to twelve horse-power double cylinder, and although there is no speed limit, there is not nearly so much reckless driving as one sees at home. Gasoline can be had in any quantity and fairly cheap, as there is any amount brought from the island of Sumatra. The cars in use, with the exception of one or two, have no magnets, but rely entirely upon accumulators and coils for the spark. An enterprising manufacturer could, it is said, do an excellent business if he entered the field and his prices were moderate, as battery troubles are common. Lubricating oils are all very good and very little trouble occurs through this source. The air-cooled motor is not a success, the weather being much too warm; the radiators upon the water-cooled machines will sometimes remain hot for days at a time. The conditions in the islands of Sumatra, Java, British North Borneo, and also the Federated Malay States, are practically the same as in Singapore Owing to the absence of railway accommodation, and in most parts there being no railways at all, the Government has spent a great deal of money in making excellent roads, and the rich natives are ready for the purchase of motor-cars.

ANGORA MOHAIR.

The mohair of Asia Minor is known and prized the world over for its soft and silky texture. The best qualities come from the provinces of Angora, Kastamuni, and Konia. The number of goats in Asia Minor, from Smyrna to the Persian borders, and from Arabia to the Black Sea, is roughly estimated at 3,000,000. No exact statistics are to be obtained as to the quantity exported last year, but the value is generally estimated at £750,000. With the exception of small quantities brought to Smyrna, the mohair which finds its way abroad is usually sent to Constantinople, and thence, through the medium of English merchants and English ships, to England. English merchants have always, more or less, been able to keep a firm hand on the mohair market. In so doing they have been able to inflict damage on the industry in Turkey, for, in spite of all the efforts of the Turkish Government to prevent it, the Angora goat was smuggled out of the country and successfully reared on the veldts of Cape Colony and Natal. In spite of the application of the most severe prohibitive measures, the Turkish authorities were powerless to do anything in the face of such exorbitant prices as were paid to the peasants for their flocks. According to the American Consul at Smyrna, more serious attention is now being paid to improved methods of rearing the Angora goat in Asia Minor. The Turkish Government has been giving assistance of late in establishing model stations for the improvement of the breed on a scientific and rational basis, as it is claimed that Angora wool, in softness, length, and durability is superior to that produced in South Africa. There is a movement on foot at present in Asia Minor to start factories in the wool-growing districts, in order that the old primitive methods of utilisation may be superseded. This will be done with a twofold object in view, namely, the creation of a means of employment for the people of those districts, and an outlet for the product at home, which will render the industry, on the whole, less dependent upon the foreign demand.

HOME INDUSTRIES.

A Co-operative Mill.—A new and interesting venture in co-operative production is now being set on foot at Hebden Bridge, in Lancashire. It appears that about a year ago the fustian weavers of that place had a dispute with their employers about wages, and went out on strike. Some 500 hands were affected, and most of them are still out of employment. There being no likelihood of settlement, it was suggested by some friends of the strikers that they should go in for joint work and joint factory ownership. The co-operative principle seems to thrive at Hebden Bridge—the Hebden Bridge Fustian Manufacturing Society of that place was one of the pioneers of the movement. A scheme was formulated, and already over 2,500 £1 shares have been taken up. A site of 48 acres has been secured, 17 of which is farmland, and the rest woodland. It includes two factories of six stories each, one a turbine factory, and the other possessing a new engine and boiler, besides several cottages. The purchase price is £3,750, and it is claimed that the rents, leaving the steam factory free, would pay 2⅝ per cent. on the outlay. The model rules of the Co-operative Union, says the *Manchester Guardian*, to whom the writer is indebted for these particulars, with special rules to meet the requirements of the society, have been sent up for registration, and it is expected that the society will be at work shortly. The site, it is said, lends itself to the making of a co-operative garden village, and the experiment will be watched with interest. The manufacture proposed will be new to the neighbourhood, and many promises of provincial support have been obtained.

The Consumption of Cheese.—It is not surprising that the manufacture of cheese is declining in this country, for there is an ever-increasing demand for milk. The average consumption per head of milk in the United Kingdom is officially estimated at 15 gallons—this is the figure arrived at as the result of two separate inquiries made for the Royal Statistical Society in 1892 and 1904 respectively, and it is adopted by the Board of Agriculture in their report just issued. It follows, since there are practically no imports of fresh milk, that the demand which British farmers have to meet is now increasing at the rate of some 6,000,000 gallons annually. It is reckoned that during the past twenty years the annual consumption of milk has increased by something like 100,000,000 gallons. This accounts for the contraction in British cheese making, for the increase in the number of milking cows, and the improved methods of management which have done something to raise the average yield per cow, are not more than sufficient to meet the growing demand for milk. It is noticeable that for the past ten years the imports of cheese have shown little tendency to increase. It is true that the total imported in 1906 was larger than in either of the two years immediately preceding—2,638,794 cwts., as against 2,442,682 cwts. in 1905, and 2,554,297 cwts. in 1904—but it was less than in 1903, when the imports amounted to 2,694,358 cwt. And if the proportional quantities of cheese per head of the population imported in 1900 and 1906 are taken, it will be found that, whilst in 1900 they were 7·4, in 1906 they were only 6·8. The conclusion, therefore, seems unavoidable that the people of the United Kingdom eat less cheese than they used to do; on the other hand, much more meat is consumed. It may be mentioned that of the total imports of cheese Canada sends no less than 73 per cent.

Dispensing Chemists.—It may be gathered from the report of the Medical Officer of Health of the City of London that a good many dispensing chemists are less careful as to the amount of water they put with their drugs than is desirable. Seven prescriptions were examined, and six were found deficient. It was found that the correct quantity of the drug was measured or weighed, but the water was simply added in amount sufficient to fill the bottle, it being assumed apparently, that its capacity is accurate. In one sample of reputed six-ounce bottles it was found that they contained on an average 5½ drams in excess of this quantity, equal to 11·25 per cent. Obviously, if the dose be measured the quantity of the drug will be diminished to this extent. To insure accuracy the water should be measured as well as the drug. It is not suggested in the report that the chemists concerned intended in any way to defraud or deceive the public. The error was due to want of thought and will doubtless be rectified now that attention has been officially directed to it.

Working Expenses.—The accounts of the railway companies for the past half year, now complete, show that there has been a moderate expansion in net earnings, not, however, in proportion to the increase in gross receipts. Whilst the gross earnings of the nineteen leading companies show an increase of 3·06 per cent.—the normal rate of growth being rather under 3 per cent.—net earnings have improved by only 1·9 per cent. Working expenses have absorbed much of the increased revenue. These expenses have been increased by (1) the rise in the price of coal; (2) advance in the price of material; (3) increase in wages; (4) betterment. Taking the twelve leading companies, it will be found that the increase in the total expenses of the half year was very much larger than for the corresponding six months of any of the preceding six years. Last year it was only £835,700; this year it was £1,186,000. The largest item in this increase is wages. For example, the wages bill of the London and North Western for the six months has increased—comparing last year with this—from £1,955,000 to £2,020,000; of the Midland from £2,052,000 to £2,136,000; of the Great Western from £1,588,000 to £1,666,000. The aggregate wages bill has increased by over £419,000, to which all have contributed with the exception of the London, Brighton and South Coast Railway, which shows a slight decrease from £368,000 to

£365,000, due to the necessity for economy even in wages consequent upon the great falling off in traffic. Next to wages, and for the moment excluding coal, the next most important item of increase is in the cost of materials. Under this head the aggregate expenditure of the twelve companies has increased £224,000. Rates and taxes make up the one item showing a decrease amounting to £58,000, or a trifle over 3 per cent. A heavy item of increase is in coal, the increase being from £2,191,000 to £2,512,000, an increase of £321,000, or about 15 per cent. The London and North Western coal bill has increased from £439,000 to £470,000; the Midland from £309,000 to £367,000; the Great Western from £294,000 to £344,000. The train mileage run shows an increase of 4,480,000 miles, or about 3 per cent. as against gross increase in the receipts of these twelve companies of about 4 per cent Fortunately, receipts for the most part showed substantial expansion, and consequently of the nineteen leading companies five have been able to increase their dividends for the past year, and ten to maintain them, four only having to reduce their distributions. The increase in capital outlay was less than usual, and in the present mood of the investor, with working expenses likely to be still further and seriously increased in the near future, directors of railway companies will, doubtless, consider it advisable to reduce their capital expenditures to the lowest possible figure.

A Cotton Trade Dispute. — Dispute has arisen between the Cotton Employers Federation and the Oldham Operatives Spinners Association upon a novel point. It was recently agreed that an advance of 5 per cent. should be paid to spinners and card-room workers. Hitherto, advances have been calculated and paid on the standard wages list, which has been in operation in the cotton districts for some years. But at present the operatives are receiving more than the standard rate, and they claim, therefore, that the advance shall be calculated from the current wages, and not from the standard rate. The employers object, and on Friday last a joint conference of representatives of masters and men was held in Manchester in the hope of arriving at a settlement. But this was not affected. The employers maintained their opposition to the claim, and the spinners will consider what further action, if any, they will take.

The Wool Trade. — The comparative ease with which the immense wool imports of last year have been absorbed is surprising. The Australian increase was 208,000 bales, mostly wools of merino quality, and the whole has been taken at very high prices. Fine wools and the tips made out of them are the firmest market. Naturally, estimates vary considerably as to what the increase in the output of Australian wool will be this year. With the exception of New South Wales, very good results are anticipated. Some estimates put the increase during the present wool year at about half that of 1906-7, whilst others reach last year's figures. It is early as yet to estimate what will happen between now and the end of June next, but with prices much above an average, supplies of Colonial wool the largest on record, and another probable large increase during the present season, consumers are not likely to hold large stocks. Prices are, on an average, more than 2d. a pound lower than last year, and there may be further decline. The great devastation caused by rabbits, in Australia, may be noted. It is difficult, says an Australian correspondent, to over estimate the evil results of this scourge. When water is abundant, and feed green, little or nothing can be done to stay the plague. Another serious evil is the increased number of foxes. Less than a generation ago, a lover of sport turned out specimens of this vermin within a few miles of Melbourne. Already they are to be found in all possible directions within 750 miles of the place where they were turned out. It is not uncommon for farmers in the best portions of Victoria to kill ten or more foxes in a single week. One farmer, with 100 lambs nearly ready for sale, is said to have had half of them killed in a single night.

The Belfast disturbances have caused a good deal of inconvenience to wholesale drapery houses in England, and to their retail customers in some parts of Ulster. Little relief has been obtained from other linen centres, so that the distribution of linens received a serious check. Fortunately the quarrel has been adjusted, and it may be hoped that it will be long before there is anything like a repetition of the late lamentable occurences.

GENERAL NOTES.

Marking Fish in Iceland.—In his report on the trade and commerce of Denmark, just issued (Cd. 3283-123), Mr. Lionel C. Liddell, His Majesty's Consul at Copenhagen, refers to some interesting experiments lately conducted by Dr. Johs Schmidt in marking plaice and cod off Iceland. Plaice to the number of 774 were marked, and 29 of these were re-caught—18 by the British, 6 by the Germans, and 5 by the Icelandic fishermen. Of 908 marked cod, 38 were caught. As only small cod were marked, the fish were caught by the coast fishermen in open boats. By means of these researches it is pointed out that it is possible to obtain some insight into the habits of the fish. Mature plaice leave the cold water off the north and east coasts of Iceland and seek the warmer water off the south and west coasts, in order to breed. The marked cod, which are not mature fish, remain in the cold water; but on attaining maturity they, like the plaice, go to the south coast to breed, *i.e.* to their place of origin. From Dr. Schmidt's observations it appears that the cod invariably spawn in the warmer waters of the south and west coasts, and the eggs and young are driven thence in a north and westerly direction. It is of

importance to have the knowledge that the cod live in the cold water of the north and east coasts from birth to maturity. In these waters trawling is impossible owing to the rocky nature of the sea bed, so that the fear expressed by the Icelandic fishermen that trawling would destroy the cod fishing is groundless.

BRITISH TRADE WITH SWEDEN.—In his report on the trade and commerce of Stockholm (Cd. 3283) Mr. Consul Villiers expresses the opinion that British trade with Sweden might be very much developed. Sweden is a country of great natural wealth, and a period of development is at hand. Most of the exports come to the United Kingdom but only a few of the imports come from here. It is not, says Mr. Consul Villiers, because Sweden is unwilling to buy, but because the traders do not know how to enter into trade with a country practically unrepresented by commercial travellers, while it is easy to enter into arrangements with the agents of the countries who are frequently calling upon them. The recent opening of the Swedish Chamber of Commerce in London may facilitate matters, but more direct steps should, in the Consul's opinion, be taken by British merchants to develop trade. The rise in value of the rated value of real estate in Stockholm is remarkable. Building is very active, and rents are enormous, and still rising. To show how property has risen in rated value in Stockholm, Mr. Consul Villiers takes figures from nine districts which represent the rated value for the years 1859, 1899, and 1904, the totals aggregating £5,135,053, £40,079,385, and £55,626,662 respectively.

TAIREN (DALNY).—Mr. Vice-Consul Parlett's report (Cd. 3283, 115) on the port of Tairen, otherwise known as Dairen, Talien, or Dalny, shows that little has been done by the Japanese to restore the town to its flourishing appearance before the war. Outside the Russian administrative quarter there are hardly any solid foreign-built houses, and the few that exist are mostly relics of the days of the Russian *regime*. The Japanese are, it is true, erecting a good many buildings, but they are poor in quality and the materials used. The greater part of the town, which was planned by the Russians on a very ambitious scale, still remains waste ground; and such streets as do exist, are occupied almost entirely by Japanese or Chinese shops, and dwellings of a poor and often squalid description. This remark applies even to the busiest streets. The attention of Japanese investors seems to have been monopolised by the great revival of trade and industries in Japan proper after the war, and to Europeans the place presents no attractions. Moreover, there is the uncertainty of tenure—Land or buildings may, by the rules now in force, be confiscated at any moment at the discretion of the authorities, one week's notice being given in the case of buildings, one month's in that of land. In addition, a lessee may not transfer his lease to another party, nor may he mortgage his rights as security for debt. The authorities indeed assure would-be lessees that the first of these conditions will never be enforced, but that is not sufficient. The merchant naturally asks why, if this be the case, the rule is not struck out.

TRADE WITH ICHANG: A SUGGESTION.—In his report on the trade of Ichang (Cd. 3283-142), Mr. Consul Little repeats what he has said in previous reports that business cannot be done by sending, as English traders are in the habit of sending, catalogues in English of all sorts of goods. It would, he says, save time, trouble, and expense, if merchants would apply in the first instance to the commercial *attaché* at Shanghai for advice. The recent receipt of an elaborately illustrated catalogue of furniture has, however, suggested to Mr. Little an idea which may possibly have something in it. British consulates in China are entirely unfurnished, and officers have to provide everything. The distances to be covered being enormous, a single journey sometimes amounting to 2,000 miles or more, with five or six transhipments, and transfers frequent, ordinary furniture does not last long. It has occurred to Mr. Little that if it were possible to make at a moderate cost steel furniture which would stand rough handling and yet be of attractive appearance, not only would British manufacturers be able to secure a considerable business now in the hands of Chinese, but a great boon would also be conferred upon consular officers and others similarly situated. To obtain the best results, the bulky articles should be made in pieces, so as to facilitate packing, or else constructed to hold the small miscellaneous things required in housekeeping so as to economise space.

COLOMBIAN BANANAS. — Reporting upon the trade and commerce of Barranquilla and Cartagena (Cd. 3283, 145), Mr. Consul Gillies says that, owing to an increased demand, thre has been an enormous development during the last few years in banana cultivation. The banana enjoys great advantages over the other products of the county in that it is more easily cultivated, and is not burdened with the large freight expenses which makes the export of coffee and other articles grown in the interior so expensive. A good deal of land has recently been bought in the neighbourhood of Santa Marta for the cultivation of the banana, and both native and foreign capital is being largely invested in the business. The United States is still the largest consumer, but there is now a good market in Europe, and it is increasing year by year. The bananas produced in the district are contracted for by the United Fruit Company of New York, and are shipped to that port weekly by vessels of the Hamburg-American line, which are specially chartered for the purpose. From all accounts the cultivation of the banana is a most lucrative investment, and the prospects for the future, in view of an ever increasing demand, are bright.

Journal of the Society of Arts.

FRIDAY, AUGUST 30, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

MULREADY PRIZE.

The Council of the Society of Arts are prepared to offer, under the terms of the Mulready Trust, a Gold Medal, or a prize of £20, for competition amongst students of the Schools of Art of the United Kingdom, at the Annual National Competition to be held in 1908.

The prize is offered to the student who obtains the highest awards in the following subjects:—

(*a.*) A finished drawing of imperial size from the nude living model.

(*b.*) A set of time studies on a small scale, from the nude living model, executed in a short time, of varied shortly sustained poses (mounted on not more than two imperial size mounts).

(*c.*) A set of studies of hands and feet from the living model (mounted on not more than two imperial size mounts).

(*d.*) Drawing from the life, including memory life drawing done at the Examination in May, 1908.

No student will be eligible for the award who does not pass in the Examination (*d*) in drawing from the life, and who does not obtain an award for (*a*) the finished drawing of imperial size from the nude living model. The other two subjects are optional.

The works must have been executed between 1st April, 1907, and 31st March, 1908.

The recipient of a prize awarded under this trust in 1892, 1893, 1896, or 1903, cannot compete again.

The drawings, &c., are to be submitted, with other school works, in the usual manner to the Board of Education, South Kensington, in April, 1908. Each competing drawing must be marked "In Competition for the Mulready Prize," *in addition* to being labelled according to the Regulations of the Board of Education.

SECTIONAL COMMITTEES.

INDIAN SECTION COMMITTEE.

The following is the list of the Indian Section Committee, as appointed by the Council:—

Sir Steuart Colvin Bayley, K.C.S.I., C.I.E. (Chairman of the Council).
Sir William Lee-Warner, K.C.S.I. (Chairman of the Committee).
Sir Frank Forbes Adam, C.I.E.
Lord Ampthill, G.C.S.I., G.C.I.E.
Sir Athelstane Baines, C.S.I.
Colonel Sir David William Keith Barr, K.C.S.I.
Thomas Jewell Bennett, C.I.E.
Sir M. M. Bhownaggree, K.C.I.E.
Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D.
Sir James Bourdillon, K.C.S.I.
Major-General Sir Owen Tudor Burne, G.C.I.E., K.C.S.I.
Sir Charles H. T. Crosthwaite, K.C.S.I.
Sir Charles A. Elliott, K.C.S.I., LL.D.
James Fairbairn Finlay, C.S.I.
Sir Frederic W. R. Fryer, K.C.S.I.
Lord Harris, G.C.S.I., G.C.I.E.
Colonel Sir Thomas Hungerford Holdich, R.E., K.C.M.G., K.C.I.E., C.B.
Sir Philip Perceval Hutchins, K.C.S.I.
Sir Seymour King, K.C.I.E., M.P.
Sir Frederic S. P. Lely, K.C.I.E., C.S.I.
Henry Luttman-Johnson.
Sir Charles James Lyall, K.C.S.I., C.I.E., M.A., LL.D.
Sir James Broadwood Lyall, G.C.I.E., K.C.S.I.
Sir James Lyle Mackay, G.C.M.G., K.C.I.E.
Sir Patrick Playfair, C.I.E.
John David Rees, C.I.E., M.P.
Right Hon. Sir Joseph West Ridgeway, G.C.M.G., K.C.B., K.C.S.I.
Field-Marshal Earl Roberts, K.G., K.P., G.C.B., G.C.S.I., G.C.I.E., V.C.
Alexander Rogers.
Sir Edward Albert Sassoon, Bart., M.P.
W. S. Seton-Karr.
Sir Charles Cecil Stevens, K.C.S.I.
Colonel Sir Richard Carnac Temple, Bart., C.I.E.
Carmichael Thomas.
Sir James Thomson, K.C.S.I., M.A.
Thomas H. Thornton, C.S.I., D.C.L.
Sir Charles A. Turner, K.C.I.E.
Alexander Falconer Wallace.
Sir George Watt, C.I.E., M.B., C.M., LL.D.
Sir Raymond West, K.C.I.E., M.A., LL.D.
Field-Marshal Sir George Stewart White, G.C.B., G.C.S.I., G.C.M.G., G.C.I.E., G.C.V.O., V.C.
Arthur N. Wollaston, C.I.E.
Lieut. Colonel Sir Curzon Wyllie, K.C.I.E., C.V.O.
Colonel Charles Edward Yate, C.S.I., C.M.G.
S. Digby, C.I.E. (Secretary).

IMPROVED METHODS OF DUST PREVENTION IN THE GRINDING TRADES.

By Samuel R. Bennett, M.A.

In the course of an investigation carried out by the order of Dr. Whitelegge, Chief Inspector of Factories, Home Office, with a view to devising methods of removing and allaying dust arising in the Sheffield cutlery and kindred grinding trades, some improvements have been made on the existing methods. Two of these improved methods are noteworthy, because their effects are far reaching. They are (1) a wet method of "racing" grindstones when first hung, and (2) an improved form of hood for catching dust, &c., given off in the processes of dry grinding.

Many varieties of grindstones are used in Sheffield. Some are huge masses, seven feet in diameter when new and twelve inches or more in thickness, and are used in saw-grinding, &c. Others are used when little more than seven inches in diameter and one inch across. Some are almost of a flinty hardness, whilst others could almost be crumbled in the hands.

The troughs in which the stones revolve are sunk into the floor so that approximately three-fifths of the stone is above the floor level, allowing for the spindle bearings over the trough. All stones are hung on spindles and centred thereon. This centering, when the stones are small, is done by means of wedges between the spindles and the central holes in the stones. For almost all wet stones above twelve inches in diameter circular side-plates are used. These are screwed up against the sides, after the rough quarried stones have been approximately balanced on the axles. The remaining irregularities, chisel-marks, eccentricities, &c., from the true cylinder, are removed by the process of "racing." To perform this operation the grinder places a short piece of wooden plank close to the face of the slowly revolving stone. Using an iron or steel rod pointed at the end as a lever he firmly holds the point against the stone; thus the projecting parts of stone are broken away. By rolling the lever on the plank the whole face of the stone is trued up. The sides are then similarly dealt with.

Up to the present time racing has been done with the stone and apparatus in a dry state. Any person who has been in a grinding hull or room whilst dry racing was being done will have experienced the suffocating clouds of swirling dust which penetrate to every corner. The dust is almost wholly siliceous, and has an irritant effect on the nostrils and throat. It covers thickly everything and everybody in the hull. Much remains suspended in the air for over an hour after the racing is finished. The baneful effect on the lungs of the grinders is easily understood.

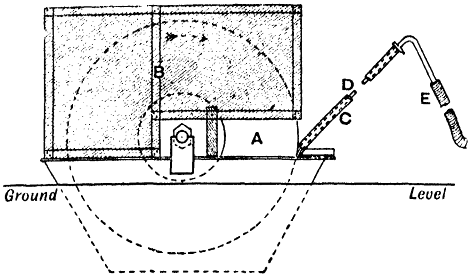
Mr. C. F. R. Johnston, H.M. Inspector of Factories, and the writer tried many kinds of apparatus—some ingenious, some expensive, most of them cumbersome—for racing a grindstone without making much dust. We found none that came within our requirements. At length we devised the following method which has the merits of being effective and cheap, and has in addition the great boon of allaying the dust almost or quite completely—a boon to grinders and machinery owners alike.

The apparatus consists essentially of an iron or steel pipe of any convenient dimensions (say, about four feet long, and about half an inch internal diameter). A piece of ordinary half-inch gas-piping has been found to answer well. Almost completely through this pipe one of smaller diameter is passed. By means of a bend, swivel or otherwise this inner pipe is connected to a flexible hose-pipe through which a supply of water can be obtained. The inner pipe may be adjusted within and prevented from slipping through the outer one by means of a collar and set-screw, sleeve, or other simple device. In conjunction with this pipe is used a box over the grindstone, to prevent splashing. This box is preferably of the length and breadth of the trough, and of such height as to allow the stone to revolve freely underneath. It may be made of wood, iron, or other waterproof material. We have found that a wooden framework covered with waterproof oiled cloth suited admirably. About nine inches deep of the lower portion of the sides and end of the box are cut away opposite to those parts of the face and sides of the grindstone where the racing tool is to be used, and to allow for the axle and bearings. It can be supported in any convenient way to make up for this.

Racing is performed with the gas-pipe in a similar manner to that with the ordinary racing-steel. A jet of water passing through the inner pipe plashes on the stone and mixes intimately with the stone dust immediately on disintegration. The amount of this water supply depends on the size and quality of the stone: a rate of a little less than one gallon per minute has been found sufficient for a stone nearly four feet in diameter, of moderate hardness.

The accompanying figure will explain the appliance.

WET RACING APPARATUS.



A = Grindstone. B = Splash Box.
C = Racing Pipe. D = Inner Tube.
E = Flexible Hose (to Watertap).

When a grinding-stone revolves with a high angular velocity a considerable whirl is produced by friction with the air in the immediate neighbourhood of the stone's periphery. If an article be pressed on its surface whereby particles of the stone and of the article are disintegrated, it will be found that the heaviest particles fly off in or near the direction of the tangent to the wheel at the grinding points. As we proceed from this tangent in the direction in which the stone is revolving, the particles get finer until some of the finest particles are carried right round the wheel by the whirl produced by the periphery of the stone. The behaviour of these particles varies according to their mass, density, the speed at which they are thrown off, and the neighbourhood of interfering objects or forces. To consider this behaviour the whole spray of particles may be divided into four classes :—

1. The heaviest, which fly nearly in straight lines for some distance, and then fall to the ground.

2. Those whose initial velocity diminishes rapidly, float about for a short time, and then settle down near the stone.

3. The lightest, which swirl from the peripheral current and float about, wafted by every eddy all over the room in which the grinding is done.

4. Those which are carried completely round the stone, and impinge again on the body or hands of the grinder, or on the article ground.

The proportions of each of these four classes in any particular case depend on :—

(*a*) Position, nature, size, shape, and speed of the stone.

(*b*) The nature, variety and size of the articles being ground.

(*c*) The amount of movement and pressure of the article on the stone.

(*d*) The situation of neighbouring objects.

(*e*) The currents of air in the room affecting the particles.

Perfect ventilation is only secured when all four classes of particles are carried away, throughout every stage of the stone's wear. This must be done in such a manner that the progress of the work in hand is not impeded by reason of—

I. Obstruction of free movement of the grinder.

II. Obstruction of free movement of the article being ground.

III. Interference with the grinder's clear view owing to the lighting of the grinding surface being cut off.

IV. Difficulty of removing the appliances fitted round the stone, to attend to it keeping in condition.

These four sets of conditions have to be satisfied in general, and in particular when the effective ventilation of any stone is being considered. The relative importance of the various conditions depends on the trades considered. In some trades the question of lighting is of prime importance, in others, of secondary, as the sparks generated by the grinding illuminate the stones sufficiently.

The removal of metallic and siliceous dust produced in quantity by rapidly revolving wheels or grindstones in the processes of grinding and glazing has always been deemed necessary for the good health of workers in these processes and those working in the same rooms. To effect such removal centrifugal fans have been almost invariably used, with ducts sucking air from the neighbourhood of the stones or wheels. Many fan plants have failed completely because, relying on the analogy of gaseous fumes, the installers have attempted to deflect the heavy dust particles by the air-suction current alone.

Observation of the actual processes, and consideration of the *vis viva* of the particles thrown off, have led to the conclusion that owing to the high initial velocity of the articles, approximating in most cases to a mile a minute, it is impossible effectually to remove dust so geherated by the deflecting power of an air current alone. In other words, it is necessary to catch the flying particles, to destroy to a large extent their initial velocity, and then to deal with them by the air current. The larger the particles given off in grinding the greater the force with which this

principle must be applied. This general principle, obvious when demonstrated mathematically, was, I believe, first enunciated in a practical manner quite recently by Mr. H. H. Cunynghame, C.B., a member of the Council of the Society of Arts. One is almost forced to conclude that this principle has been unknown to all, or certainly to the great majority of ventilating engineers, judging from the construction of the plants installed. As a rule attempts have been made to catch one or two of the four classes of particles, usually the first two. In order effectively to remove these without obstructing the lighting of the grinding surface, the hood fitted to the extremity of a fan-duct opposite a stone has been placed at a comparatively great distance. Thus the third class of dust is only partially deflected, whilst the fourth is left unaffected. The consequence is that the most deleterious dust is left to be inhaled by the workers.

Again, sometimes the hood is fixed so as to intercept classes 2 and 3, leaving classes 1 and 4 in the working room.

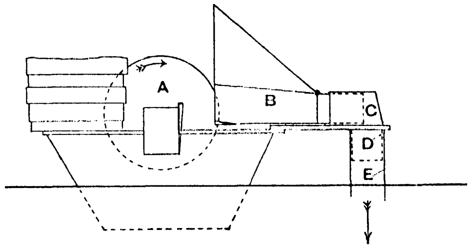
In no case has a hood capable of adjustment so as to intercept the fourth class been fitted, allowing at the same time of the grinding surface being illuminated.

Founded on the foregoing considerations, the following novel form of hood for dry grinding of razors, scissors, forks, augers, gimlets, &c., was devised by Mr. Johnston and the writer. It has been tried and found effective in many instances.

It consists of a board or plate having a hole at one end, and means of connecting this aperture so as to form an air-tight joint to the fan-duct. Over this aperture is fixed a pipe of slightly larger area than the air-duct. Into this slides a similar pipe on to which a suitably shaped hood is fitted. This hood, which may have its top and sides constructed with glass panes to allow light to pass to the grinding surface, is kept with its lower edge close to the stone, and preferably overlaps the stone on either side. The device depends for its efficacy on the following points of construction. First the height of the opening is such that the upper edge is above the tangent to the stone at the furthest backpoint on the stone at which grinding may be done, thus catching class 1 dust; second, the width is the minimum consistent with the width of the stone and the extent to which dust is ejected sideways by oblique grinding; third, the slope of top and sides is allowed for, so that all particles shall strike the hood at an oblique angle and be reflected further into the hood; fourth, the bottom comes close up to the stone, thus deflecting the air and fine dust whirl of the stone periphery and sides towards the duct; fifth, the top and sides may be constructed of easily removable strong sheet glass, ensuring translucency, with wire netting on each side to prevent fracture; sixth, as the stone wears down, the hood can be drawn forward so as to intercept class 4 dust throughout the stone's wear; seventh, the hood may be made capable of a second adjustment on the fan-duct; the top of the hood may have hinges at its juncture with the sliding pipe, and so be raised or lowered as the size of the stone requires.

The accompanying figure will illustrate the appliance.

ADJUSTABLE HOOD.



A = Grindstone. B = Adjustable part of Hood.
C = Fixed part of Hood. D = Adapter to Fan Pipe.
E = Fan Pipe.

GEOGRAPHY AND COMMERCE.*

Peculiar importance in commercial geography is given to the relations between the regions that yield or yielded spices and those in which they were consumed at a great distance from the place of origin, and one of the most important facts in human history is that for many hundreds of years an extremely valuable trade in these commodities was carried on between India and the Mediterranean. Spices, no doubt, were less talked about, less prominent as symbols of wealth, than gems and jewels, fine woods and ivory, but they formed the basis of a larger trade, which was in the aggregate probably more profitable than that in the still more costly wares.

The geographical relations between India and the Mediterranean necessarily determined the routes followed by this traffic. These routes were singularly few. They were practically confined for the most part to minor variations in two main routes, one by way of the Red Sea, the other by the Persian Gulf. At more than one period of history, in very early times,

* Abstract of the address of George C. Chisholm, M.A., B.Sc., President of the Geographical Section before the British Association, at Leicester.

in the days of the splendour of Assyria and Babylonia, and again in the flourishing days of the Caliphs of Baghdad, the Persian Gulf route had a peculiar advantage in the existence of the large and rich populations that afforded an intermediate market; and another important fact in the relations of geography and commerce, one that has had vast effects on human history, is that the physical conditions of the area between the head of the Persian Gulf and the Mediterranean are, and throughout human history have been, such as to make the most convenient outlet of that route some point or points on that seaboard which in ancient times was known as Phœnicia. Between that seaboard and the Euphrates the desert is sufficiently narrowed to be most easily crossed. The most favoured outlets on this seaboard were not always the same. They varied in different circumstances, which gave a different geographical value now to one point, now to another.

Although the geographical conditions for a long period of time led to a special accumulation of the wealth due to commerce on Phœnicia, Phœnician trade promoted the growth of wealth and civilisation elsewhere. The Greeks of the Ægean distinctly recognised what they owed to the Phœnicians, and they in their turn derived much wealth from Eastern trade, even though not so directly as the Phœnicians, and they in their turn derived some of the food for a commercial population from the far west—from Syracuse, Sybaris, and even the distant Kume. But the far east had a peculiar fascination. As the articles from which much of the wealth of commerce was derived originally came from India, it was natural that the idea should arise that India was a wealthy country, a country well worth possessing. I am not aware whether India ever was in historical times a wealthy country in the sense of producing a great abundance of the necessaries and ordinary conveniences and comforts of life in proportion to the population, but if it was not rich itself it was at least the means of making others rich. There can hardly be a doubt that the desire of possessing this country of real or imagined wealth was prominent among the motives that led Alexander the Great to embark on that enterprise which had such surprisingly—one might almost say miraculously—widespread, profound, and lasting effects on the history of the Near East.

At the outset of his career Alexander had destroyed Tyre, thinking, no doubt, that he had thereby wiped away the claims of one rival for a share of the wealth of the East; but it is a noteworthy fact that he did not thereby destroy the value of the site of Tyre under the conditions which then subsisted. Tyre revived and again obtained wealth from its trade with the East, as it did again and again in subsequent history. A heavier blow to Tyre than its mere destruction was the ultimate accomplishment of Alexander's idea for founding a great seat of commerce on the harbour which he saw could be created in the neighbourhood of the Nile delta. The foundation of Alexandria and the successful efforts of the successors of Alexander in Egypt to divert a large part of the trade in spices and other Oriental goods to the Red Sea route for the Mediterranean did more than a single act of war to deprive Tyre and other Phœnician cities of the peculiar pre-eminence which they had long enjoyed in the trade in those wealth-bringing commodities.

But perhaps the history of Venice shows even more clearly than that of Tyre the importance of this eastern trade in connection with certain inevitable geographical relations. The foundation of the future commercial glory of Venice may be said to have been laid when Rome planted her colonies north of the Po. The gradual clearing of forests gained for agriculture to a greater and greater extent one of the most favoured agricultural areas in Europe. There resulted a superfluity of agricultural products, which begot a trade by sea. Gradually commerce grew, until in the eighth century we find the Venetians trading with Syria and Africa, Constantinople, and the ports of the Black Sea.

Throughout the period of growth the policy of this trading republic, both by land and sea, is very significant. Venice early realised the force of Bacon's maxim, "that he that commands the sea is at great liberty, and may take as much and as little of war as he will." Power at sea was necessary to provide security for her commerce. In her early times she generally owned allegiance to the Eastern Roman Empire, a suzerainty which could do her little harm and could and did do her much good. To that allegiance she adhered until she was strong enough to turn against and reap advantage from the overthrow of her suzerain. At an earlier date, before the close of the tenth century, she had conquered Dalmatia, and thereby destroyed the hordes of pirates who had found refuge in the innumerable harbours of that coast and constantly harassed the commerce of the Adriatic. At every opportunity she secured establishments and acquired possessions in the Levant.

As a last illustration of the nature of the relations of Venice to the North Italian plains we may refer to some of the points mentioned in a celebrated and often quoted address delivered to the principal senators of Venice by the Doge Mocenigo just before his death (1423), at the time at which Venetian trade was at the very height of its prosperity. At that time Venice was in possession of a considerable tract of adjacent territory on the mainland, and there was a party favourable to further action on the part of Venice against the growing power of Milan. The aged and sagacious Doge feared that this party was going to gain the upper hand and elect as his successor Francesco Foscari, who, he thought, would involve them in dangerous and disastrous as well as useless enterprises. The immediate occasion of the conflict of views in the Venetian Senate was a request of the Florentines for support against alleged designs of the Duke of Milan. Mocenigo, however, not only warned the senators in the most earnest and urgent language against Foscari personally, but also advised them against the particular enterprise, maintaining

that it was of no consequence even if the Duke of Milan made himself master of Florence, since the artisans of Milan would continue to send their manufactures to Venice, and the Venetians would be enriched to the loss of the Florentines. He then went on to give particulars of the trade of Venice at that time, dwelling specially on the value of that with Lombardy. To Lombardy alone, it appears, Venice sold every year cloths to the value of 400,000 ducats, *tele* (? linens) to the value of 10,000 ducats; wools of France and Spain to the value of 240,000 ducats, cotton to the value of 250,000 ducats, wine to the value of 30,000 ducats, cloth of gold to the value of 250,000 ducats, soap to the same value, spices and sugar to the value of 539,000 ducats, dye-woods to the value of 120,000 ducats, other articles 110,000 ducats; in all, goods to the value of more than 2,500,000 ducats, the profit amounting to quite half a million ducats. With the exaggeration that comes natural to a lover of his country Mocenigo goes on to say rather grandiloquently that to the Venetians alone land and sea were equally open; to them only belonged the carriage of all riches; they were the providers of the entire world.

The clearest evidence of the supreme importance of the Indian trade to the Italian cities is to be found in the results of the discovery which finally diverted from Venice and the Mediterranean the great bulk of the Indian trade until that trade had lost all the special significance which it had retained for thousands of years. It need hardly be said that I refer to the discovery of the sea way to India by the Portuguese in 1497-9. Efforts to avert the results of the great achievement of the Portuguese were vain. Other disasters befel the Republic about the same time. Not only was commerce taking another direction, but, says Romanin, "the wars of Italy were emptying the treasury, the Turkish power was despoiling the Republic step by step of its possessions beyond the sea, and Venice was beginning to descend that incline which was to reduce it to a subordinate position among the powers of Europe." North Italy generally suffered at the same time. The withdrawal of the greater part of the spice trade, by diminishing the growth of wealth among the inhabitants, made that part of the world a less important market for manufactured goods. Countries outside of Italy, where rival manufactures had already started, were increasing their wealth more rapidly, and thus imparting an increasing stimulus to their manufactures, and these increased while those of Italy declined. In 1338 the number of woollen factories in Florence is given at 200, making in all 70,000 to 80,000 pieces of cloth in the year; in 1472 the number of shops or factories had risen to 270, but no estimate is given of the quantity of the product; in 1529, however, the number of shops is said to have sunk to 150, and the quantity of cloth manufactured to 23,000 pieces per annum, and in the latter half of the eighteenth century the quantity was only about 3,000 pieces annually.

The main point on which I want to insist is that, whatever the commodities were, whether carried out or home, the nature of the trade with the East was little if at all altered by the discovery of the direct route to India by sea. The trade still continued to be one concerned in a moderate number of articles of small bulk but high value. It was merely a change of route that the Portuguese effected, and for more than a hundred years they remained in sole command of this route. After that, however, they were ousted from the greater part of this trade, and that the more valuable part, chiefly by the Dutch, and from a geographical point of view it is very interesting to note how the Dutch did it. They did not trouble themselves much about India proper. They left the Portuguese alone at Goa, and from that port as a base allowed them to pick up as much trade as they could at Calicut and Cochin, which, said Albuquerque, "were capable of supplying the Portuguese fleets until the Day of Judgment." But Malacca, on the straits of that name, gave command of the route to the further East, whence came in the end even larger quantities of pepper than could be got from India, whence came too ginger, cloves, and nutmegs, as well as the products of China. The importance of this place Albuquerque had accordingly recognised, and in 1511, the year after he took Goa, he took it also by the right that always belongs to the lion as against the jackal. This place was taken by the Dutch (1641), who had previously established themselves on Java and the Spice Islands, where they maintained an absolute monopoly. Ceylon, again, was (and is) almost the only place from which the true cinnamon was to be obtained, so the Dutch took that island also from the Portuguese (1656). As long as the Portuguese were the sole Europeans in the East, Calicut and Cochin not merely furnished the Portuguese with Indian wares, but were important entrepôts for the spices, perfumes, drugs, and jewels of the Further East as well as of Chinese silks and porcelains; but the trade in these commodities could be wholly or largely diverted to places in the possession of the Dutch. Even before the capture of Malacca and Ceylon a Portuguese Viceroy had reported (1638) that the Dutch had a monopoly of trade from the Bay of Cochin China to the Point of Sunda.

But this change also was little more than a change of route. The general character of the Eastern trade remained the same. The English East India Company, whose operations, through the hostility of the Dutch, came to be restricted to India proper, there founded a trade that gave much more opportunity for expansion under modern conditions than that of the Dutch, but for a long time it retained the same character. All the commodities enumerated by Colquhoun as brought back by the voyages of 1620-3 in exchange for the bullion and merchandise sent out were pepper, cloves, mace, nutmegs, Chinese and Persian raw silk, besides calicoes, the sole manufactured article, and one of course that had relatively

a much higher value than now, when the direction of the trade in that commodity is reversed.

A similar character for a long time belonged to the trans Atlantic trade, even though the costs of transport in that case were less, and favoured the development of a trade in somewhat bulkier commodities. Furs from the Far North, tobacco from Virginia, sugar, and afterwards coffee and cotton from the West Indies, were by far the most prominent imports. It was the tobacco trade of Virginia that first enabled Glasgow, which at the time of the union of the English and Scottish Parliaments was an insignificant town with less than 13,000 inhabitants, to convert itself into a seaport, and thus lay the foundations of its subsequent prosperity. Now tobacco makes up less than 1 per cent. of the value of the goods imported at Glasgow, and, though that may be partly due to a diminution in the actual quantity of tobacco imported at Glasgow, this result has chiefly been brought about by changes in relative values. A hundred years ago the value of the imports into Great Britain and Ireland from the British West Indies was about one-fourth of the total value of the imports from all parts; now it is less than 1 per cent. of that value.

What has brought about such changes, what makes the essential difference between recent and all previous commerce, is the series of enormous improvements in the means of communication which followed so closely on the invention of textile machinery and the improvement of the steam-engine in this country. These improvements have had two important effects on commerce. First, they have facilitated the maintenance of order and security both by land and sea, and thus enormously reduced the risks of commerce. Secondly, they have directly lowered the cost of transport for different goods in different degrees. Bulky goods of little value could now for the first time be profitably conveyed many hundreds of miles by land to a seaport, and there load ever larger ships for distant shores, thus opening up markets with vast undeveloped resources in the heart of great continents. Along with these bulkier goods the more valuable goods are carried at a cost far below that of former times, so that for such commodities as pepper the mere freight is almost a negligible item.

CAMPHOR PRODUCTION IN FORMOSA.

The manufacture of camphor in Formosa is confined to trees of upwards of fifty years of age. The Camphor Bureau prohibits the cutting down of trees of less age than fifty years. Although inquiries as to the number of old trees in the island are not as yet completed, the number of these trees is far less than was stated a few years ago. Recent investigations warrant the statement that the supply of old trees will, at the present rate of cutting, become exhausted in less than fifty years. The old trees now standing are confined to the moutainous eastern half of the island, in regions for the most part part still under the control of savage tribes. The work of subjugating these tribes is difficult, and one requiring much time. At the present rate of subjugation it will be many years before their territory can be safely exploited. Besides the subjugation of savage taibes, there are other difficulties to be overcome. The mountains are covered with dense jungles, and the work of building roads in order to render the camphor forests accessible to profitable exploitation is one requiring the expenditure of much labour and time. Moreover, the sanitary conditions throughout much of the territory are such as to materially reduce the efficiency of labour employed therein. A Japanese company took one thousand coolies into the Daito district a few years ago for the purpose of exploiting the camphor forests. Reports from this company state that 33 per cent. of its labour is incapacitated through the contraction of fevers. Last year twelve of its men were decapitated by head-hunting savages. At present, according to the American Consul at Tamsui, the greater part of the camphor produced in the island comes from the trees in the Toen prefecture. With prosperous conditions obtaining throughout the civilised portions of the island, there is naturally a reluctance on the part of the coolie labourer to risk attacks by savages in working in the camphor forests at a wage equivalent to about 1s. 8d. a day, when he is enabled to secure half this amount in the more peaceful pursuits on the lowlands. Thus the difficulties to be overcome in order to exploit the remaining camphor forests of the island are such as to render the cost of securing the product a constantly increasing quantity. The Camphor Bureau of the Formosan Government expects to produce 6,667,000 lbs. of crude camphor, and about one-half that amount of camphor-oil during the present year. They expect to produce a similar quantity each year during the next few years, with probabilities of a slight increase thereafter. It is said that Formosa at present produces about 75 per cent. of the world's supply of camphor, the remaining 25 per cent. being produced by Japan and China. Until Japan took possession of the island, practically nothing was done to replace the trees cut down, except what was done by nature itself. The camphor tree grows readily from seed, and requires but little attention. Since the organisation of the camphor monopoly in 1899, the Formosan Government adopted a system of afforestation which it is hoped will result in guaranteeing to the island a constant supply of raw materials. The Camphor Bureau provides three methods of afforestation—Government replanting, replanting by schools, villages and agricultural societies, and replanting by private concerns Up to the present year the securing of seeds was difficult. While the Formosan trees are good seed producers, yet owing to the fact that the seed ripens quickly, and if not picked within two days after it blows away, much difficulty has been experienced in col-

lecting seeds, as the trees were not afforded the proper protection. Owing to the large export of Japanese seeds to foreign countries, the Formosan authorities could not depend upon Japan for a supply. The Camphor Bureau now designates and registers certain of the seed-producing trees and prohibits them being cut down; in this manner a plentiful supply of seeds is being provided for. Agricultural experiment stations are maintained throughout the island, and to these is assigned the task of planting the seeds and providing nurseries for the young plants. The young plants are taken from these nurseries and replanted in districts set apart for that purpose. It required several years to secure sufficient trained coolie labour to attend to the setting out of these trees. Since 1900 the Government has planted about 3,000,000 young trees, and has arranged to add 500,000 to their number during the present year. It is expected to be able to plant 750,000 each year after the present year. Trees planted in the mountainous districts are set out with the idea of prohibiting their utilisation for camphor production for a period of 40 or 50 years. Those which are planted on the lowlands are set close together in rows with the idea in view of utilising their leaves, after they have attained a ten years growth in the manufacture of the crude camphor. The lowlands planted in camphor are designated as camphor gardens rather than as camphor forests. Beyond an occasional clearing of the ground about the young tree, it requires no attention in the way of cultivation or irrigation. There are many varieties of worms which attack the young plants, but the Government experts report that but six trees, out of many thousands planted, die. There are two varieties of trees—the camphor-producing tree, and the camphor-oil producing tree. The former is the more valuable. It requires an expert to detect the difference between these two varieties in the standing trees. The Government nurseries furnish young plants to the schools, villages, and agricultural societies desirous of planting the camphor trees, and many such have availed themselves of this offer. Private concerns in Formosa desirous of engaging in the camphor industry, are also supplied by the Government nurseries with the young plants. Hence it is evident that afforestation of camphor in Formosa is proceeding at a good pace. Reports from Japan estimate the number of trees planted there during the past ten years at 8,000,000. Reports from China state that while the Chinese are interesting themselves in the question of afforestation, up to the present nothing has been done towards the planting of new trees. Crude camphor is manufactured from the wood by the simple process of distillation. Chips of camphor wood are placed in a clay-plastered retort which rests upon a circular wooden rim of a water pan. This water pan is placed over a fire. Connected with the retort, at some distance away, are the crystallisation and cooling boxes in which the camphor vapour passes, is cooled, and crystallised. The camphor thus crystallised is dark in appearance, and is known as crude camphor. Stills or stoves are erected as close as possible to the supply of the raw material, hence there is a very considerable number of them. The products of the different stoves are not uniform in quality. The Monopoly Bureau works in Taihoku a camphor factory, where the products of the various stoves are graded, and by redistillation rendered uniform. This factory produces two grades of camphor, known as "B" and "B B" grades. The "B" grade, that which is exported to the American market, is rated crude camphor, containing a higher percentage of oil and water than the "B B" grade, which more nearly approaches a refined camphor. The "B B" grade differs from properly refined camphor in that it is not clarified. Owing to the fact that the Monopoly Bureau's plant was partially destroyed by fire a few months ago it has been impossible to produce the "B B" grade, and consumers are obliged to take the "B" product until the plant is repaired. The crude camphor which is not exported to foreign markets is sent along with the camphor oil to the Kobe refineries where refining is completed. Although the "B B" grade is rated by the American customs examiners as a refined camphor, yet the Camphor Bureau in Formosa terms it crude camphor, for the reason that a clarifying process is necessary to the completion of the refining. It may be said that Formosa, in conjunction with Japan, holds a monopoly of the production and sale of the world's supply of camphor. Although the customs returns for China show that there were exported from that country during the year 1906 about 12,000 piculs (1,600,000 pounds) of crude camphor, yet the Formosan industry fears no competition from that source. Reports of camphor planting in Ceylon, Florida, Texas, and Mexico do not disturb the prospects of the Formosan products in the eyes of the Formosan authorities. These contend that the more camphor trees there are planted the less likelihood there will be of the successful production of an artificial substitute. Artificially produced camphor seems to be a reality, but it is contended that its cost of production is too great to warrant its being made to enter into competition with the natural camphor. The bulk of the world's camphor production goes into the manufacture of celluloid. It is estimated that about 70 per cent. of all camphor produced is utilised in the manufacture of celluloid. Owing to the difficulties which many manufacturers of celluloid have experienced in securing enough camphor to meet their demands, these have often been obliged to purchase supplies through brokers. The Formosan Government now declares its intention of remedying this state of affairs, to some extent at least. The Camphor Bureau has instructed its selling agents to supply, first and foremost, its customers among the celluloid manufacturers. As Japanese capital is already engaged in the erection of celluloid factories in Japan, it is only to be expected that the Japanese

manufacturers will also come in for their *pro rata* share of raw materials. Each year a contract is made with an agent for the disposal of the products of the Bureau.

OLD-AGE PENSIONS.

There has just been presented to Parliament tables which have been prepared in connection with the question of old-age pensions, with a preliminary memorandum. It has been felt, says a prefatory note, that a collection of various statistics bearing upon different aspects of this question, would be of service, "even if the figures collected are only regarded as material for consideration by those who wish to examine fully into the matter." For the last fifteen years Parliament has been directing its attention, in one way or another, to this question of old-age pensions, and as far back as 1893 there was a Royal Commission on the Aged Poor "to consider whether any alterations in the system of Poor-law relief are desirable in the case of persons whose destitution is occasioned by incapacity for work resulting from old age, or whether assistance could otherwise be afforded in such cases." Then there was the Committee on Old-Age Pensions appointed in 1896, and presided over by Lord Rothschild, followed by the Select Committee on Aged Deserving Poor (1899), the Departmental Committee on Aged Deserving Poor of the same year, and the Select Committee on the Aged Pensioners Bill, 1903. But although various pension schemes for the aged poor in this country were propounded and considered between 1893 and 1903—some of a universal kind, some on a basis of insurance (with or without an element of compulsion), and others involving special conditions, limiting the number of possible pensioners—there is as yet no scheme which has, after consideration by a Parliamentery Committee, taken so definite a shape, and reached so authoritative a position, as that favoured by the Select Committee of 1899 (Mr. Chaplin's), and virtually adopted, with modifications, by the Select Committee of 1903. The present Blue-book, therefore, refers to the question of the numbers which might now be pensionable under the scheme, having regard to the investigations made by the Departmental Committee of 1899-1900. Further, the opportunity is taken of making some observations on points affecting the matter, such as the number and growth of the aged population. In considering these figures, it is necessary to remember the want of actual facts, and of accurate statistics bearing on many of the points. The calculations often rest upon assumptions sometimes open to question. The following Table shows in the briefest possible form the conclusions arrived at:—

Estimated number of persons over 65 years of age in 1901	2,016,000
Deduct:—	
For those whose incomes exceed 10s. a week..	741,000
For paupers	515,000
For aliens, criminals, and lunatics ..	32,000
For inability to comply with thrift test	72,700
Total deductions	1,360,700
Estimated number of pensionable persons	655,000
Total estimated cost in round figures	£10,300,000

Bringing the figures down to the present time, it is estimated that in the United Kingdom, out of a total population of the age of 65 years and upwards, probably numbering some 2,116,000 in 1907, there would be about 686,000 persons qualified for a pension, leaving about 1,430,000 persons of pensionable age who would be disqualified on one or other of the grounds specified in the scheme of Mr. Chaplin's Committee, and that the total cost for the United Kingdom, including 3 per cent., or £313,977, for administrative expenses, would be, in round figures, £10,780,000.

It must be borne in mind that a not inconsiderable section of the population is already in receipt of pensions or superannuation allowances from one source or another, though neither the exact number of persons, nor the proportion of those who are over 65 years of age, can be stated. Under the head of "Army, Navy, and Civil Service Pensions," the Chancellor of the Exchequer, when questioned on the subject last year, gave the number as about 171,815, and the cost at £7,903,369. From a return presented to the House of Commons in 1906, it appeared that 24,244 former employees were, on the 31st March, 1906, receiving pensions or superannuation allowances from local authorities in England and Wales, the largest section of pensioned officers by local authorities in England and Wales consisting of police pensioners, who may be estimated to number about 17,000. Information as to the number of persons receiving pensions or superannuation pay from Friendly Societies is very limited. The general evidence given before the several committees which have considered the question of old age pensions goes to show that old age pay, as such, is comparatively little given; the form of benefit derived by aged members is that of permanent sick pay. From a return of 1898, it appeared that £611,464 was annually derived from endowments applicable to pensions and alms-houses, so far as the Charity Commissioners were cognizant of such charities. This return has recently been brought up to date by the Charity Commissioners, who calculate that the total amount applicable to pensions and alms-house charities in England and Wales is not less, and is probably more, than £661,000 at the present time. Summarising the figures referred to in the foregoing statement, it will be found that they cover 249,213 pensioners, who are estimated to draw in pensions in one year £10,532,256. The present report

assumes as highly probable that the number of persons at present in receipt of pensions, and other similar allowances, from one source or another, in the United Kingdom, is "well over" 250,000, and one reason for this conclusion is that full information as to certain classes, *e.g.*, those in receipt of sick pay or old age pay from Friendly Societies, and from pension charities, is not obtainable. Another reason is that the figures take no account of persons receiving pensions and allowances from former private employers, nor of those benefiting under superannuation schemes of business firms or companies. It must not be forgotten that a large section of the persons here referred to are in receipt of pensions, or superannuation allowances, to which they have themselves contributed.

Some reduction in the expenditure on Poor-law relief has usually been assumed, whether as an immediate, or a more remote, result of schemes of old-age pensions. There is a general agreement in the reports of the various committees who have considered the question of old-age pensions, that the cost of indoor relief would be practically unaffected by the operation of a pension scheme. The only appreciable saving in Poor-law expenditure would be in the portion which relates to out-door relief, amounting in 1904-5 to £3,265,000, to which must be added £532,000, the salaries of officers, and minor incidental expenses connected with the administration of out-door relief. The present report does not commit itself to any definite opinion as to what saving might be anticipated, but it is pointed out that in regard to any possible saving some part of the cost of out-door relief consists of medical relief, which is more particularly necessary in the case of the aged, and it is unlikely that the cost to the Poor-law of medical relief would be diminished. And in any saving of Poor-law expenditure, urban and rural unions would be somewhat differently affected. The number of paupers 65 years of age and upwards, in proportion to the total population of the same age, varies greatly in different parts of the country, and the number is usually higher in rural than in urban areas. The report does not discuss the very important question as to how, assuming them to be decided upon, old-age pensions are to be paid, nor does it specifically recommend any particular scheme. The estimated cost of the Chaplin Committee scheme, with its many deductions, has been given above. Assuming a scheme of universal character, the report finds that the total number of persons, aged 65 and upwards in 1907, may be put at 2,116,000, and that the cost of granting a pension of 5s. a week to all persons of this age without distinction would, at the outset, amount for the United Kingdom to £27,508,000, apart from the cost of administration. This amount would be equivalent to a poll-tax of about 12s. 6d. per head on the total estimated population (1907) of the United Kingdom. The cost of pensions granted universally to persons of 70 years and upwards, would amount to £16,302,000, the estimated numbers of that age being 1,254,000. The cost, at a later date, after the scheme had become operative, would be affected only by the natural growth of the aged section of the population, and in 1921 would be, as estimated by the report, £30,632,000 for all persons 65 years and upwards.

INDIAN COFFEE.

The production of coffee in India is restricted for the most part to a limited area in the elevated region above the south-western coast, the coffee lands of Mysore, Coorg, and the Madras districts of Malabar and the Nilgiris, comprising 86 per cent. of the whole area under coffee cultivation throughout the country. There has been a decrease in the estimated area in each year since 1896, and in the three years, 1904-6, both inclusive, there has been a net decrease of 21,564 acres.

But while the area has been steadily diminishing, the exports, which account for the greater part of the crop, rose steadily in the five years ending 1905-6, and were greater in that year than in any year since 1888. In 1906-7, however, unseasonable rains were reported from nearly all the principal coffee-growing districts, and the total quantity exported (25½ million lbs., as against 40⅓ million lbs. in 1905-06) decreased by over one-third.

It is difficult, if not impossible, to arrive at any estimate of the quantity of coffee consumed in India, but it must be considerable, for, in Southern India at all events, there are none but the poorest, who do not drink coffee, and no bazaar so small that coffee is not procurable. There is also a steady export of about two million pounds to Ceylon, indicating a large and regular consumption, which is probably a commensurate indication of the demand among the natives on the western side of Palk's Straits.

The two chief markets for Indian coffee are the United Kingdom and France; but no Indian coffee went direct to the United States, although that country consumes nearly one-half of the total quantity of coffee exported from all the countries of the world.

The total number of persons employed on the coffee estates in 1896 was 70,521, or at the rate of one person to every 2·8 acres.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department, Admiralty, in July, 1907:—

New Charts.—No. 1543—England, east coast:—Yarmouth and Lowestoft roads, Yarmouth haven, Lowestoft harbour. 3656—Baltic:—Giedser Rev and approaches to Nysted. Plan:—Warnemünde Harbour. 3619—British Columbia:—Moresby passage to Gabriola pass, southern sheet. 205—Plans in the Red Sea:—Mersa Fejer, Mersa, Daiúr, Mersa

Kihai. 22—Persian Gulf:— Kuweit harbour and approaches. 3662—Philippine islands. Plans on the north-west coast of Luzon:—Port San Esteban and Nalvo bay; Santiago cove, Darigayos inlet, Solvek cove. 1961—Formosa, west coast:—Pescadores islands. 3652—Korea, west coast:—Amunyoku kan (Yalu river). 3650—Japan, Honshu (Nipon), south coast:—Toba ko. 1175—South Pacific ocean; sketches of anchorages in the Tuamotu or Low archipelago:—Ahii or Peacock island, lagoon entrance; Manihi entrance; Tokea or Takaroa, lagoon entrance; Amyot bay, Avatoru entrance, Tiputa entrance; Mururoa or Osnaburg island; north passage to Rotoava; Fakahina island; passes into Amanu atoll; Pakaka (Aniuru) pass; Pakaka to Seignelay point. 3664—South Pacific ocean; passes and anchorages in Tuamotu or Low archipelago:—Raroia pass and anchorage; Makemo island, north-east pass and anchorages; Tahanea island passes.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners.

1859—England, west coast:—King road. 355a—United States, east coast:—Chesapeake bay. 1496—Bahamas:—Great Bahama bank, sheet I. 2077—Bahamas:—Sheet IV., from Exuma to New Providence. 2431—Alaska:—Port Simpson to Cross sound. 2458—Alaska:—Port Simpson to port McArthur. 3252—Central Africa:—Victoria Nyanza, northern portion. 755—Bay of Bengal:—False point anchorage. 1338—Pescadores islands:—Inner anchorages. 1798—China, north coast:—Kwang tung peninsula, &c. 2833—China, north coast:—Port Adams. Hulu shan bay. 997—Japan:—Yokoska harbour. 752—Japan:—Owasi bay to Takamatsu no saki. 3565—New Zealand:—Bream head to Tepaki point. 214—Solomon islands.

These charts are issued by Mr. J. D. Potter, 145, Minories.

PAUPERISM.

The official statement as to the position of pauperism in England and Wales at the end of June, just issued, shows some diminution in the number of paupers relieved, as compared with the same months in preceding years. Not only was the number of persons in receipt of poor relief slightly lower than in 1905, the tendency to decrease was most marked in the later months, the decline in London being greater than in the rest of the country. But the number of paupers is still comparatively high. The rate of pauperism to population stood at 26·7 per 1,000 on the 1st January, 1907. This was a lower rate than in the two previous years, when it was respectively 27·1 and 27·6, but higher than in 1904, when it was 26·0, having been as low as 24·8 in 1901. These per-centages relate to the whole of England and Wales. Taking London alone, the per-centage which was 27·4 in 1901, and had steadily risen until it was 31·7 in 1906, fell to 30·8 in 1907, being still considerably higher than the per-centage for the whole of England and Wales. The general decline of pauperism in England and Wales, in comparison with a number of periods in the not very distant past, is shown in the following figures. The average rate of paupers relieved per 1,000 of population in the quinquennial period 1872-1877, was 35·4; in 1885-1892, 25·6; in 1902-1907, 26·4. While out-door pauperism in 1907 shows in the aggregate a decrease as compared with 1906—15·8 against 16·3—the increase in indoor pauperism which marked the preceding years is maintained. The number of the indoor paupers in London increased by over 100 per cent. between 1872 and 1907—72·370 against 36·175, exclusive of insane and casual paupers. The same class in provincial unions has increased by over 75 per cent. in the same period—176·575 against 100·652—but the rise has been at a noticeable high rate in the last decade than in earlier years. The number of out-door paupers shows a corresponding decline as compared with the indoor poor. The rate of pauperism to population shows a greater increase in London than in provincial unions during the years 1902 to 1905, and the decline in London since the latter date has also been more marked. The total number of persons relieved as lunatics or idiots on the 1st January, 1907, was 110,613, being 12 per cent. of the whole number of persons chargeable to the poor-rate. A larger proportion of the total pauperism in the urban than the rural districts of this class, *e.g.*, in London 17 per cent., Lancaster 14 per cent., York, West Riding, 12 per cent., as compared with 9 per cent. in Norfolk, and 8 per cent. in Suffolk. The average in the numbers of the insane between 1st of January, 1906, and 1st January, 1907, amounted to 1·8 per cent. in England and Wales.

DEVELOPMENTS IN ELECTRIC INCANDESCENT LAMPS.*

The author gave a short description of the latest developments made in the manufacture of incandescent electric lamps, and exhibited, amongst others, samples of graphitised carbon lamp, the Gem, Nernst, Osmium, Tantalum, Osram, Tungsten, Yust and Hannaman's lamps, Kuzel, Zircon-Wolfram (several types), including also a sample lamp called by the inventors (Prof. Parker and Mr. Clark) the "Helion" lamp, and shown for the first time in England. Owing to the high efficiency of these lamps, Mr. Gaster predicted that the expense for electric lighting will be greatly reduced in the near future, and that better illumination will be obtained.

* Abstract of a paper read by Leon Gaster before Section G of the British Association at Leicester.

Some of the lamps shown consume less than one-third of the energy required by the ordinary carbon incandescent lamps, which means enormous saving. The progress made this year was remarkable. Many manufacturers on the Continent are ready to supply large quantities of these new metal filament lamps, and in England the Robertson Lamp Manufacturers are extending their works with a view of making these lamps here. The "Z" Electric Lamp Syndicate are about to manufacture the filaments to be used in the "Zircon Wolfram" lamp in this country. Mr. Gaster pointed out the desirability of lamp makers supplying lamps combined with suitable shades and reflectors in one unit so as to assist consumers in obtaining any desired effect of illumination, either by concentration or diffusion. Particular attention was drawn to the need for manufacturers and large consumers of light to adopt proper methods of illumination, the advantages of this being many, viz.: First, the sight of the people will be improved and prolonged; secondly, the output will be quite appreciably increased; and thirdly, the quality of the work done under proper illumination will be of the same standard as when done in the day-time. The economies derived by not using proper methods of illumination are false economies, when one bears in mind the fact that the expense of providing and keeping up proper illumination is in most cases only a small fraction compared with the value and the nature of the work turned out. This question of defining the proper amount of light necessary for different purposes will form the work of the illuminating engineer. For the creation of this new specialist the author is a strong advocate.

Reference was made to the useful work for improving the quality of incandescent lamps, and towards helping the consumers in obtaining more satisfactory illumination done by the Engineering Department of the National Electric Lamp Association, and by the Electric Testing Laboratories of New York.

OPENINGS FOR FARMING IMPLEMENTS IN MANCHURIA.

Manchuria is expected within a short time to be a good market for nearly all kinds of modern agricultural machinery and appliances, as the northern part of the country is very fertile, and embodies exceedingly large tracts of as rich agricultural land as can be found in any part of the world. This land up to the present time has only been cultivated in the old crude Chinese way, and there are many large areas which are still in a virgin condition. Settlers are flocking in from other and more densely-populated parts of China, but until modern implements are introduced to the farmers' notice, by samples and practical demonstration of their utility, the old conditions will doubtless continue to prevail. The American Consul at Newchwang says that as the land in the vicinity of that place is marshy and practically unfit for farming purposes, it would be difficult for the merchants there to get into touch with the farmers, even if samples of agricultural machinery were available. For that reason it would not pay the machinery merchant to take the matter up on his own account, as to do so he would be obliged to take the samples some hundreds of miles up country, and give practical demonstrations, which would only be possible by obtaining a special expert for the purpose. The northern Chinese are firm believers in a "chop"—that is, if they adopt or get into the way of using a certain brand of anything, and if it suits their purpose, they will continue to use that particular chop or brand, so long as they can get it, in preference to any other, and it is difficult to get them to change, even to an improved article, for they know what the article they have used can do, and are sure that it will satisfy their requirements, while with any other chop or brand there is an element of uncertainty, and they prefer to be sure rather than to run any risk of being sorry later on. This makes it obvious that the manufacturers who first get their goods will reap the greatest benefit, and have very litttle trouble in holding the trade thereafter. The port of Newchwang has greater advantages for supplying the Manchurian market than any other, the main competitors being Vladivostock and Dalney. The former is dominated by Russians, who are not to be greatly feared owing to their having to transport their supplies long distances by railway; the latter place is controlled by the Japanese, who are ambitious, enterprising, and are losing no opportunity to secure for themselves the trade of Manchuria; but they are also at a disadvantage in being obliged to depend on their railways for the transportation of everything into the interior, while Newchwang has the advantage of being able to reach a large section of the country by Chinese junks which ply on the river Liao and its tributaries for eight months in the year and deliver freight at much lower rates than the railways can possibly do. Manchuria has been greatly handicapped for the past fifteen years by political troubles, which seriously retarded the progress and development of the country; but now the political horizon is clearing, and the inhabitants are turning their attention to farming and other industrial pursuits with renewed zeal, which will undoubtedly lead to a greater prosperity than was ever known before; and especially with the influx of new settlers, the country has great possibilities in both farming and mining, and it is believed that within a very few years, it will be one of the best markets for agricultural machinery and farming implements in all Asia. Whether the demand will be supplied by America or Europe will depend entirely upon the enterprise shown by the manufacturers themselves, for as already intimated those who first get their goods introduced will be hard to depose, even though others may offer superior goods.

ARTS AND CRAFTS.

Industrial Art in Sweden.—In the intervals between the great international exhibitions, though we have from time to time opportunities of looking at what is being produced in France and Germany, we see very little of the productions of the smaller European nations. Their wares are largely made for home consumption, and of those which go abroad, more find their market in the United States than in Great Britain. Meanwhile these countries are not by any means standing still; they are in some ways far more keenly interested in art movements than we are ourselves, and far more eager to be in the front rank in matters connected with industrial art. If we look at what is being done in Sweden at the present day, we see that, in spite of an intensely strong national feeling, the work turned out in the other countries of Europe has not only been keenly watched, but closely studied, and, in some cases, imitated. There is the same desire to be up to date; the same continual struggle to be original at all costs which characterises so much of the work nearer home.

Two very powerful and in many respects quite opposing influences are apparent in modern Swedish industrial art—the modern spirit and the national and patriotic feeling. Swedish painters have, for the most part, studied in Paris, and have brought back with them modern ideas and notions in abundance, and in Sweden it is not uncommon for artists who have achieved some measure of success in pictorial work to turn their attention either to decoration or to applied art. On the other hand, there has arisen of recent years a very strong movement (the force of which seems to have been very greatly increased by the rupture with Norway) in favour of retaining, encouraging, and reviving the old national and traditional forms of design—more especially in weaving, embroidery, and jewellery. Of course, the two movements have not been altogether in the same sphere—that towards modernity has been current mainly in architecture, decoration, and design for manufacture, while the stronghold of the traditional and patriotic movement has been in the more simple crafts which we should call "Home arts and industries." Still there come points where the two meet, and the result, though not always satisfactory, is at least interesting. It leads in design to something which without being exactly affected is rather mannered, and it must be admitted that at times it goes very near to incoherence.

Swedish Furniture.—Mnch of the modern Swedish furniture is frankly on the lines of that being made in England and France, some of it, following the taste which seems to be rather fashionable just now all over Europe, is a kind of Swedish imitation of the Empire period, and is interesting from the fact that it is, as it were, individual in spite of itself. While the would-be original work is quite often commonplace, it happens by the irony of fate that what is meant to be a copy has, as a rule, some real claim to individuality. In a country so well wooded as Sweden it is only natural that workers in wood should have developed certain little tricks of workmanship which are characteristically their own. These characteristic touches are, however, naturally enough, still more noticeable in the modern versions of the old peasant furniture which are now, thanks in part to work of the *Svensk Hemslöjd* very often to be seen. There is, indeed, in some quarters quite a fashion for this old Swedish peasant furniture, roughly made and painted (generally in blue or green), with perhaps some slight carving about it and completed by additional painted ornament of what is meant to be a naturalistic kind. Deliberately rude cupboards, tables, and chairs of this description hardly look out of place even in quite modern conntry houses in Sweden, and they have a certain charm of their own. It is only when they are surrounded by the luxury usually associated with a large town that they seem out of keeping.

The still more simple carpenter's work is very often most ingenious. Slightly carved garden benches are habitually made with backs which can be turned in either direction, on the plan of the seats of a London electric tram-car; there are also various forms of simple shelves and cupboards being made, as well as pieces of furniture designed to serve as either tables or chairs, which would be well worth imitating by people interested in home arts in our own country. The work is often primitive enough, but it is of the kind which should be within the power of most carpentry classes, and, in its simple way, it is both effective and pleasing.

Swedish Embroidery and Embroidery and Hand-loom Weaving, &c.—We are proud in England of the revival which has taken place in embroidery, hand-loom weaving, lace making, and textile handwork generally. It is, therefore, rather a shock to find the same movement even more fully organised in Sweden than it is with us.

As regards very fine embroidery and gold thread work there is, of course, little in Sweden to compare with what is being done at home, though, following the tradition of the country, they still make very excellent use of inlay where we should content ourselves with appliqué.

Swedish lace, though interesting as the survival and revival of a traditional industry, is not in itself ordinarily very beautiful or very fine in workmanship.

In the coarser kinds of embroidery, however, a good deal of interesting work is being done, and that too not only by individual workers, but in big shops and ateliers, and on a surprisingly large scale.

Not only, as with us, are artists of repute willing to make designs for embroidery, but the larger societies and institutions, such as *Handarbetets Vänner* and the textile department of *Nordiska Companiet*, employ quite a number of designers—some of whom are attached to one particular society, while others work independently. It does not appear to be the

fashion to encourage the workers to make their own designs.

Of the patterns, both for weaving and embroidery, a large number are of a traditionally Swedish character owing, perhaps, rather more to patriotic feeling than to any desire to imitate what is old. Indeed, those designs which are not on old lines are generally very modern in feeling. The methods of workmanship, and even the colours employed are, in the main, the old ones.

Perhaps the most interesting kinds of work from an English point of view are the appliqué embroidery, and the kind of woven fabric which is called in Sweden *Flossa*. They are both developments of peasant work. Much of the embroidery, and especially the appliqué, is done on felt or cloth; and most effective work is produced by appliqué of different coloured cloth, sometimes couched, sometimes stitched, sometimes just run, on to a cloth ground. There is a great deal more variety of colour in this simple, rather barbaric, Swedish appliqué than in any work of the kind done in England. It is rather odd that, in opposition to this, some of the best fine work is in white silk on a white or unbleached ground. The design, however, of much of this white embroidery, which is at first sight almost Oriental looking, proves on examination to be in the manner of old Swedish work. In the *Flossa*, which is woven in a hand loom, the pattern is raised, and is formed by different coloured threads, worked into the warp and left upstanding in loops (like terry), which are afterwards cut, and give the effect of a pattern in pile on a ground of woollen material. The fabric is very effective, and eminently suitable for chair-backs and small covers or rugs.

The patterns used in the ordinary hand-loom weaving are rather different from those most in favour in England, and very great use is made of the chequer, which proves to be the basis of many designs, in which, at first sight, it hardly seems to occur at all. A good deal of tapestry weaving is also being done, but it seems unlikely that there can be any great demand for work of this kind at a price which would make it worth while to produce it. There appears to be a certain amount of energy wasted in encouraging crafts which are, after all, remains of a bygone condition of life—one might almost say of a past age of civilisation. But it must be remembered that in Sweden, in some of the country districts at least, "home arts" are not things of the past which have to be or less laboriously revived, but existing occupations of the peasant folk more or less in danger of being ousted from their place by the competition of machine-made goods. It may be, and probably is, quite good policy to encourage the country to weave for themselves the things which they use, to teach them in so doing to choose what is artistically good instead of bad, and may be to help them to dispose of any goods which they may be able to make over and above what they need for their own homes. But how far it is wise to encourage tapestry weaving and other industries, by means of which are produced, with great labour, effects not unlike those which could be (though they often are not) obtained in machine-made fabrics, is much more uncertain. Such work is just now more or less the fashion. Whether there will continue to be a sale for it at a price which will enable the workwoman to earn a living is an open question, and one which, in the light of the impetus being given to such work at the moment, demands rather serious consideration.

CORRESPONDENCE.

EFFECT OF IRRIGATION ON ALKALI SOILS.

I was glad to see Mr. Wright's letter on the above subject in the *Journal* for August 16th, and a profitable discussion would ensue if gentlemen with expert knowledge of practical experience in the matter, not only in India but in other countries where irrigation on a large scale is practised, could be induced to state their views. So far as the great irrigation colonies in India are concerned there is no immediate danger of serious damage due to the deterioration of alkali soils under irrigation, but there appears to be considerable diversity of opinion as to the proper methods to employ in the application of irrigation to alkali soils so as to minimise the danger of bringing the salts to the surface in excessive quantities and so spoiling the land for cultivation. And as it is the case that individual colonists have suffered considerable loss in places owing to unsuitable treatment of their allotments, a comprehensive inquiry into the subject conducted by a qualified agricultural engineer should be productive of good results. L. ROBERTSON.

NOTES ON BOOKS.

EMBROIDERY AND TAPESTRY WEAVING. By Mrs. A. H. Christie. The Artistic Craft Series of Technical Handbooks. London: John Hogg.

This is a very workmanlike little book. The author knows her subject, and sets to work to tell what she knows with as little padding as possible. After a short preface and introduction, one chapter on tools and another on pattern designing (which, by the way, contain between them more controversial matter than all the rest of the book put together), she proceeds to describe at length, with the help of adequate diagrams, the various stitches and methods of work, and concludes the embroidery section of her book with chapters on "the garniture of work" and "practical directions."

Readers have learned to expect that in serious books on embroidery the stitches will be methodically and carefully grouped, and our hopes, on the whole, prove to be well founded in this volume—though it is rather difficult to see why two such radically different sets of stitches, as satin-stitch and buttonhole, should have been grouped together to form a chapter.

Mrs. Christie's sympathies would appear to be rather with fairly bold work executed in the hand than with very fine embroidery done in a frame—and she devotes a good deal more space to describing the various chain-buttonhole, knot, herring-bone, and other fancy-work stitches—which have been adequately explained before by other writers, than to giving directions for the production of good effects in satin-stitch or couching - though she has not neglected this part of her task. The sections which treat of drawn threadwork, cut and open work, darning on net, open work fillings, quilting, &c., help to make the book more complete than most volumes on embroidery.

There are admirable hints on how best to use the stitches described, and a much-needed chapter on garnitures; but it is somewhat of a surprise to be told that "even more than simpler work applied embroidery needs the work of some light finish upon the ground."

Mrs. Christie's studies seem to have led her mainly in the direction of English work. She tells about English knotted line work in which "the knotting was executed in the thread previously to embroidering with it," but she makes no mention of the frequent occurence of this little fraud in Chinese work. Her description of the stitch employed for the famous Syon Cope is thorough, and she seems to look upon the use of some such method as quite within the range of practical present-day politics.

Tapestry weaving is far less fully treated than embroidery, occupying only about fifty pages out of over three hundred and fifty. The directions given for setting up the loom and starting work, as well as for executing small pieces of work in an ordinary embroidery frame, are thoroughly clear and practical. The necessary tools and materials are carefully described, and the difficulties and limitations of the craft are sufficiently indicated.

The volume is well illustrated. Of the 16 collotype plates, many might with advantage be on a larger scale – these are not, however, the most important part of the illustrations. The description of the stitches, methods of work, &c., are liberally supplemented by diagrams in the text, drawn by the author herself, and these are so clear and so practical, that in many cases it is an easy matter to see exactly how a stitch is worked without referring to the text at all.

THE TOURIST'S INDIA. By Eustace Reynolds-Ball. London: Sonnenschein and Co. 1907.

The author has produced a well illustrated volume, which he claims to be not a guide-book, but a popular sketch of the present-day topographical, archæological, historical, and social aspects of the great show cities and tourist centres of India. At the same time, he is careful not to assume a very profound knowledge of India and Indian affairs on the part of tourists and others.

Wintering in India, owing largely to improved conditions of travel, has become increasingly popular, but the tourist is warned that he must not compare India with Egypt, except to the disadvantage of the former as a health resort owing to the fluctuations of temperature. "For real invalids, India is altogether unsuited; semi or quasi-invalids, with due precautions as to locality, regimen, &c., will probably benefit by a winter sojourn; while ordinary travellers, provided they follow a few common-sense rules about diet and clothing, will derive much pleasure and profit from a winter in India." The Indian Government, with a view of encouraging tourist traffic, grant specially reduced rates for certain specified circular tours, thus the tourist may visit Calcutta, Benares, Lucknow, Cawnpore, Delhi, Agra, Jhansi, Gwalior, and back to Calcutta, *vià* Cawnpore and Allahabad, at the low first-class fare of ten pounds fourteen shillings. The total cost of this flying visit, including second-class fare (P. and O.) London to Calcutta, is worked out at £100.

Some practical information is given in the appendix, and a clear map of the Indian Empire is added.

WRITING, AND ILLUMINATING, AND LETTERING. By Edward Johnston (with Diagrams and Illustrations by the Author and Noel Rooke). London: John Hogg. (Artistic Craft Series of Technical Handbooks.)

The increased interest in writing, illuminating, and lettering, at the present day explains the very remarkable development of one of the minor arts. There is a considerable number of old books on penmanship, but most of these books are too full of flourishes, intended to glorify the writing-master rather than to make pleasant-reading manuscripts. The chief object of the new movement is legibility combined with beauty. One effect of the revival of interest in beautiful handwriting is the production of manuscript books, a movement in which the late William Morris was a leader.

Mr. Lethaby, the general editor of the series, remarks: "Of all the arts writing, perhaps, shows most clearly the formative force of the instrument used. In the analysis which Mr. Johnston gives us in this volume nearly all seems to be explained by the two factors – utility and masterly use of tools. No one has ever invented a form of script, and herein lies the wonderful interest of the subject; the forms used have always formed themselves by a continuous process of development."

The author writes: — "Generally, this book has been planned as a sort of 'guide' to models and methods for letter craftsmen and students, more particularly for those who cannot see the actual

processes of writing, illuminating, &c., carried out, and who may not have access to collections of MSS."

The effect of carrying out this scheme has been the production of a fully-illustrated book, with minute instructions as to tools and examples which ought to be of the greatest value to those who wish for full information on this fascinating subject. Handwriting is a subject that has been too long neglected; now it has been taken up by enthusiastic teachers. Mr. Johnson well says:—"The Roman alphabet is the foundation of all our alphabets, and since the full development of their monumental forms about 2,000 years ago the Roman capitals have held the supreme place among letters for readableness and beauty. They are the best forms for the grandest and most important inscriptions." Nowhere is there a finer presentation of Roman capitals than is to be seen in the inscription on the base of the Trajan column at Rome (A.D. 114).

It will be remembered that Mr. Johnston read a paper on "Calligraphy and Illumination" before the Applied Art Section of the Society on January 31st, 1905.

THE CAUSES OF DECAY IN A BRITISH INDUSTRY. By "Artifex" and "Opifex." London: Longmans, Green, and Co. 1907.

In this work the authors set forth in considerable detail their views of the decay of the great Birmingham gun trade. The titles of the different chapters give an idea of the object of this book: Making an Industry; Decline of the British Industry; Some Causes of the Decay; Economic Production; Home Legislation affecting Production; Home Legislation affecting Trade with the United Kingdom; Home Legislation affecting the Export of British Manufactures; Indian and Colonial Legislation affecting Imports of British Goods; British and Foreign Trade with Foreign Countries; American Trade and Industry; Governments in Business. The authors claim to show "from records other than the Board of Trade Returns, how the industry was established, how it grew and thrived in Great Britain. For nearly half a century there are records of the annual output from the Birmingham district, and from these and a mass of independent collateral evidence, the authors prove beyond a doubt that the industry is declining in Great Britain. They are able to show also that the world's annual output is actually increasing."

GENERAL NOTES.

BRITISH INSURANCE COMPANIES IN URUGUAY.—More than two-thirds of the total fire insurance in Uruguay is transacted with British companies, whose premium incomes may be roughly estimated at sums ranging from £25,000 to £2,000,000. Referring to this subject in his report on the trade of Uruguay for 1906, Mr. R. J. Kennedy, His Britannic Majesty's Minister at Monte Video, says (Cd. 3283-116) that as regards fire companies the British offices have an overwhelming majority, no less than 18 of the best-known British offices being represented at Monte Video against three French, three German, and three Argentine companies. In maritime insurance, too, the British are in a majority there, three British companies occupying the field as against one German, and one Italian firm. As regards life insurance there is comparatively little business as yet done in Uruguay. The actual figures which would show the proportionate premium incomes are not available, but the competition for healthy business is keen, and there are few desirable fire and marine risks which are not covered by insurance. On the other hand, Mr. Kennedy is informed that there are in Uruguay not more than 2,500 life policies in force, the country having about 1,000,000 inhabitants. The public have not yet been "educated up" to the advantages of life insurance. Even when a life policy is taken out it is usually an endowment policy. "El que verga atras que arregle," a Uruguayan saying equivalent to "Après moi l'deluge," is typical of the feelings of most inhabitants of Uruguay towards life insurance. The taxes levied upon life insurance companies are an annual license of £42 upon native and of £84 upon foreign companies. There is also a tax of 2 per cent. upon the premiums of insurance done by native fire and marine companies, and of 4 per cent. upon foreign companies. Life insurance companies pay ½ per cent. in the case of native and 2 per cent. if foreign, calculated upon a similar basis.

ROYAL SANITARY INSTITUTE.—The 44th course of lectures and demonstrations for Sanitary Officers will be given in September-November, 1907. The course comprises the following lectures:—Part I.—Four lectures on Elementary Physics and Chemistry in relation to Water, Soil, Air, and Ventilation, and Meteorology. Twenty-one lectures on Public Health Statutes; Orders, Memoranda, and Model By-Laws of the Local Government Board and the By-Laws in force in the Administrative County of London. The Practical Duties of a Sanitary Inspector, *e.g.*, drawing up notices as to Sanitary Defects, Drain-Testing, Disinfection, Methods of Inspection, Note-taking, Reporting, and Elementary Statistics. Municipal Hygiene or Hygiene of Communities, including Prevention and Abatement of Nuisances, Sanitary Defects in and about Buildings and their Remedies, Water Supplies, Sanitary Appliances, Drainage, Refuse Removal and Disposal, Offensive Trades, Disinfection. Building Construction in its Sanitary Relations, Local and Physical Conditions. Measurement and Drawing Plans to Scale. Inspections and demonstrations are arranged in connection with the lectures. Part II.—Seven lectures on Meat and Food Inspection, including Taking of Samples of Water, Food, and Drugs for Analysis. Practical Demonstrations of meat inspection are given.

Journal of the Society of Arts.

No. 2,859. VOL. LV.

FRIDAY, SEPTEMBER 6, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

EXAMINATIONS.

The Results of the Elementary Examinations (Stage I.) have been issued, and copies have been sent to all Examination Centres for distribution to candidates. The Examination Programme for 1908 will be ready in about a fortnight.

STOCK PRIZE.

FOR THE DECORATION OF PART OF THE INTERIOR OF A BUILDING.

The Council of the Society of Arts are prepared to offer, under the terms of the Stock Trust, a Gold Medal, or a Prize of £20, for competition amongst the students of the Schools of Art of the United Kingdom, at the Annual Competition to be held in 1908.

The Prize is offered for the best original designs for an Architectural Decoration, to be carried out in painting, stucco, carving, mosaic, or any other process.

This Architectural Decoration is to be for the side of a room or a hall, a ceiling, the apse or side of the chancel of a church, or any suitable part of the interior of a building.

The designs must be on imperial sheets. Each set must consist at least of a coloured drawing to scale of the whole design of decoration, and two coloured drawings of details on separate imperial sheets. Mere patterns or sketches of details, without the mouldings or borders necessary to make up a complete decorative scheme, will not be taken into consideration. The designs must have been made between 1st April, 1907, and 31st March, 1908.

The recipient of a prize awarded under this trust in 1893 or 1897 cannot compete again.

The designs are to be submitted, with other school work, in the usual manner, to the Board of Education, South Kensington, in April, 1908. Each of the imperial sheets, forming a set of competing designs, must be marked, "In competition for the Stock Prize," in addition to being labelled or staged according to the Regulations of the Board of Education.

SECTIONAL COMMITTEES.

COLONIAL SECTION COMMITTEE.

The following is the list of the Colonial Section Committee, as appointed by the Council:—

Sir Steuart Colvin Bayley, K.C.S I., C.I.E. (Chairman of the Council).
Sir Westby B. Perceval, K.C.M.G. (Chairman of the Committee).
Earl of Aberdeen, G.C.M G.
Hon. Sir William Arbuckle, Agent-General for Natal.
Lord Belhaven and Stenton.
Thomas Jewell Bennett, C.I.E.
Lord Blyth.
Lord Brassey, G.C.B.
Byron Brenan, C.M.G.
Sir Thomas Fowell Buxton, Bart., G.C.M.G.
Hon. Sir John A. Cockburn, K.C.M.G.
T. A. Coghlan, I.S.O., F.S.S., Agent-General for New South Wales.
Captain R. Muirhead Collins, R.N., Representative of the Commonwealth of Australia in London.
H. Bertram Cox, C.B.
Edward Dent.
Rt. Hon. Sir Charles Wentworth Dilke, Bart, M.P.
Hon. Alfred Dobson, Agent-General for Tasmania.
Hon. Sir Charles W. Fremantle, K.C.B.
Hon. Sir Thomas E. Fuller, K.C.M.G., Agent-General for the Cape of Good Hope.
Sir Robert Giffen, K.C.B., LL.D., F.R.S.
Right Hon. Sir George Goldie, K.C.M G., D.C.L., LL.D.
Robert Kaye Gray.
W. L. Griffith.
Sir John J. Grinlinton.
Sir Charles Augustus Hartley, K.C.M G., M.Inst.C.E.
Sir Clement Lloyd Hill, K C M G., C B., M.P.
Sir Francis J. S. Hopwood, K.C.B , K.C M.G.
Hon. J. G. Jenkins, Agent-General for South Australia.
Sir Alfred L. Jones, K.C.M.G.
Sir Charles Malcolm Kennedy, K C.M G., C.B.

Sir Nevile Lubbock, K.C.M.G., Chairman of the West India Committee.
Charles Prestwood Lucas, C.B.
Sir E. Montague Nelson, K.C.M.G.
Sir Montagu F. Ommanney, K.C.M.G.
Sir Gilbert Parker, M.P.
Hon. Cornthwaite Hector Rason, Agent-General for Western Australia.
Hon. W. Pember Reeves, High Commissioner for New Zealand.
Viscount Ridley.
Right Hon. Sir Joseph West Ridgeway, G.C.M.G., K.C.B., K.C.S.I.
Alexander Siemens.
Sir John Smalman Smith, M.A.
Hon. Sir Richard Solomon, K.C.B., K.C.M.G., K.C., Agent General for the Transvaal.
Earl of Stamford.
Lord Strathcona and Mount Royal, G.C.M.G., LL.D., High Commissioner for the Dominion of Canada.
Sir Thomas Sutherland, K.C.M.G.
Hon. J. W. Taverner, Agent-General for Victoria.
Carmichael Thomas.
Hon. Sir Horace Tozer, K.C.M.G., Agent-General for Queensland
Sir William Wood Treacher, K.C.M.G.
Sir Charles Rivers Wilson, G.C.M.G., C.B.
Sir J. Wolfe-Barry, K.C.B., F.R.S.
Sir Frederick Young, K.C.M.G.
S. Digby, C.I.E. (Secretary).

MINES OF THE WORLD.

The fourth part of the Home Office Report on Mines and Quarries for 1905 containing Colonial and foreign statistics has lately been published.

The particulars are compiled from various official and unofficial sources. Great difficulties in preparing this part of the volume arise either from want of adequate official statistics or from the lateness of their publication. In several cases the statistics for 1905 were not received until the present year was far advanced.

The general results are summed up (1907), and though the figures are not complete, they are sufficient to give a fair general idea of the relative importance of mining in each country.

According to Table 284 the number of persons engaged in mining and quarrying at home and abroad in 1905 exceeded five millions. Of this total, roughly speaking, nearly one-fifth were employed in the United Kingdom and more than one-third in the British Empire. It should be noted, however, that no statistics are published by several countries, *e.g.*, Bolivia, Brazil, China, Persia, Roumania and Turkey, in which mining is carried on, or for the ore mines and quarries of the United States, and the figure in this Table probably falls considerably short of the real total.

More than half of the total number were employed in getting coal alone, Great Britain employing over 843,000, the United States 626,000, Germany 548,000, France 175,000, Belgium 135,000, Austria 119,000, and India nearly 90,000.

Table 285 summarises the world's output of the most important minerals in 1905. The total amount of coal produced was 941 million tons, the value of which is estimated at more than 305 million pounds sterling. The quantity and value compared with 1904 show an increase of more than 55 million tons and 10 million pounds sterling respectively.

The following figures show the main sources from which the fuel supply of the world is obtained: —

Country.	Quantity.		Value.	
	Metric Tons.	Increase or Decrease on 1904.	£	Increase or Decrease on 1904.
		Metric Tons.		£
United States	356,454,000	+ 37,258,000	97,897,000	+ 6,650,000
Great Britain	230,918,000	+ 3,760,000	82,030,000	− 1,813,000
Germany	173,811,000	+ 4,360,000	58,611,000	+ 1,313,000
Austria-Hungary	42,454,000	+ 1,923,000	10,462,000	+ 387,000
France...	35,928,000	+ 1,760,000	18,562,000	+ 385,000
Belgium	21,775,000	− 986,000	11,007,000	− 459,000

Gold shows an increase of 63,960 kilograms, the total output being 580,087 kilograms (18,650,217 ozs.) of which the value is estimated at over 79 millions sterling. The British Empire supplied nearly 59 per cent. of the output; Australia contributing 19½ per cent., the Transvaal 26⅓ per cent., and Canada 3¼ per cent. of the total. The United States contributed 22¾ per cent.

In the case of iron, the United States, with an output of 23⅓ million tons, is considerably ahead of any other country. The German Empire, with 6 million tons, and Great Britain, with about 4¾ million tons, come next. It is important to point out that the quantities of the other metals included in this Table are those which are considered otainable from the ores raised in the countries in question, and must not necessarily be taken as a measure of their metallurgical industries.

The value of the world's output of copper is about equal to the combined value of the outputs of silver, tin, and zinc. The total value of the figures shown in the Table giving a summary of output of minerals and metals may be roughly taken as representing over 700 millions sterling.

The next Table shows the loss of life from accidents in mines and quarries, and the death-rates from accidents per 1,000 persons employed. Taking coal mines, for which the figures are fairly complete, it will be seen that the death-rate of the United Kingdom is 1·35, and for the British Empire 1·34; while for France it is 1·04, for Germany 2·05, and for the United States 3·45. The death-rate for foreign countries generally is 2·40.

In the case of gold mines, complete figures are only available for the British Empire. They show a considerable increase in the death-rate from 2·55 in 1904 to 3·58 in 1905.

HISTORY OF THE DEVELOPMENT OF ELECTRIC MOTIVE POWER.*

There is one last example of the interaction of science and industry which may claim closer attention. In the history of the development of the electric motor one finds abundant illustration of both aspects of that interaction.

We go back to the year 1821, when Faraday, after studying the phenomena of electromagnetic deflexion of a needle by an electric current (Oersted's discovery), first succeeded in producing continuous rotations by electromagnetic means. In his simple apparatus a piece of suspended copper wire carrying a current from a small battery, and dipping at its lower end into a cup of mercury, rotated continuously around the pole of a short bar-magnet of steel placed upright in the cup. In another variety of this experiment the magnet rotated around the central wire, which was fixed. These pieces of apparatus were the merest toys, incapable of doing any useful work; nevertheless they demonstrated the essential principle, and suggested further possibilities.

Two years later, Barlow, using a star-wheel of copper, pivoted so that the lowest point of the star should make contact with a small pool of mercury, found that the star-wheel rotated if a current was sent through the arm of the star, while the arm itself was situated between the poles of a steel horseshoe-magnet. Shortly afterwards Sturgeon improved the apparatus by substituting a copper disc for the star-wheel. The action was the same. A conductor, carrying an electric current, if placed in a magnetic field, is found to experience a mechanical drag, which is neither an attraction nor a repulsion, but a lateral force tending to move it at right angles in the direction of flow of the current and at right angles to the direction of the lines of the magnetic field in which it is situated. Still this was a toy.

Two years later came the announcement by Sturgeon of the invention of the soft-iron electromagnet, one of the most momentous of all inventions, since upon it practically the whole of the constructive part of electrical engineering is based. For the first time mankind was furnished with a magnet the attractive power of which could be increased absolutely indefinitely by the mere expenditure of sufficient capital upon the iron core and its surrounding copper coils, and the provision of a sufficiently powerful source of electric current to excite the magnetisation. Furthermore the magnet was under control, and could be made to attract or to cease to attract at will by merely switching the current on or off; and, lastly, this could be accomplished from a distance, even from great distances away. How slowly the importance of this discovery was recognised is now a matter for astonishment. To state that Sturgeon died in poverty twenty-six years later is sufficient to indicate his place among the unrequited pioneers of whom the world is not worthy. Six years elapsed, and then there came a flood of suggestions of electric motors in which was applied the principle of intermittent attraction by an electromagnet. Henry in 1831, and Dal Negro in 1832 produced see-saw mechanisms so operated. Ritchie in 1833 and Jacobi in 1834 devised rotatory motors. Ritchie pivoted a rapidly commutated electromagnet between the poles of a permanent magnet—a true type of the modern motor—while Jacobi caused two multipolar electromagnets, one fixed, one movable, to put a shaft into rotation and propel a boat. A perplexing diminution of the current of the battery whenever the motor was running caused Jacobi to investigate mathematically the theory of its action. In a masterly memoir he laid down a few years later the theory of electric motive power. But in the intervening period, in 1831, Faraday made the cardinal discovery of the mechanical generation of electric currents by magneto-electric induction, the fundamental principle of the dynamo. Down to that date the only known way—save for the feeble currents of thermopiles—to generate electric currents had been the pile of Volta, or one of the forms of battery which had been evolved from it. Now, by Faraday's discovery, the world had become possessed of a new source. And yet again, strange as it may seem, years elapsed before the world – that is, the world of engineers – discovered that an important discovery had been made. Not till some thirty years later were any magneto-electric machines made of a sufficient size to be of practical service even in telegraphy, and none were built of a sufficient power to furnish a single electric light until about the year 1857. In the meantime in America other electric motors, to be driven by batteries, had been devised by Devonport and by Page; the latter's machine had an iron plunger to be sucked by electromagnetic attraction into a hollow coil of copper wire, thereby driving a shaft and flywheel through the intermediate action of a connecting-rod and crank. Page's was, in fact, an electric engine, with 2-foot stroke, single-acting, of between 3 and 4 horse-power. The battery occupied about 3 cubic feet, and consumed, according to Page, 3 lb. of zinc per horse-power per day. This must have been an under-estimate; for if Daniell's cells were used the minimum consumption for a motor of 100 per cent. efficiency is known to be about 2 lb. of zinc per horse-power per hour.

Electric Motive Power Impossible in 1857.

Upon the state of development of electric motors fifty years ago information may be gleaned from an exceedingly interesting debate at the Institution of Civil Engineers upon a paper read April 21st, 1857, "On Electromagnetism as a Motive Power," by

* Extract from the Address of Professor Sylvanus Thompson, D.Sc., F.R.S., to the Engineering Section of the British Association at Leicester.

Mr. Robert Hunt, F.R.S. In this paper the author states that, though long-enduring thought has been brought to bear upon the subject, and large sums of money have been expended on the construction of machines, "yet there does not appear to be any nearer approach to a satisfactory result than there was thirty years ago.". After explaining the elementary principles of electro-magnetism, he describes the early motors of Dal Negro, Jacobi, Davenport, Davidson, Page, and others. Reviewing these and their non-success as commercial machines, he says :—"Notwithstanding these numerous trials . . . . it does not appear that any satisfactory explanation has ever been given of the causes which have led to the abandonment of the idea of employing electricity as a motive power. It is mainly with the view of directing attention to these causes that the present communication has been written." He admits that electromagnets may be constructed to give any desired lifting power; but he finds that the attractive force on the iron keeper of a magnet of his own, which held 220 lbs. when in contact, fell to 36 lbs. when the distance apart was only one-fiftieth of an inch. To this rapid falling off of force, and to the hardening action on the iron of the repeated vibrations due to the mechanical concussion of the keeper, he attributed the small power of the apparatus. Also he remarked upon the diminution of the current which is observed to flow from the battery when the motor was running (which Jacobi had, in his memoir on the theory, traced to a counter electromotive force generated in the motor itself), and which reduced the efficiency of the machine. "All electromagnetic arrangements," he says, "suffer from the cause named, a reduction of the mechanical value of the prime mover, in a manner which has no resemblance to any of the effects due to heat regarded as a motive power." Proceeding to discuss the batteries, he remarked that as animal power depends on food, and steam power on coal, so electric power depends on the amount of zinc consumed; in support of which proposition he cited the experiments of Joule. He gives as his own results that for every grain of zinc consumed in the battery his motor performed a duty equivalent to lifting 86 lbs. 1 foot high. Joule and Scoresby, using Daniell's cells, had found the duty to be equivalent to raising 80 lbs. 1 foot high, being about half the theoretical maximum duty for a grain of zinc. In the Cornish engine, doing its best duty, 1 grain of coal was equivalent to a duty of raising 143 lbs. 1 foot high. He put the price of zinc at £35 per ton as compared with coal at less than £1 per ton, which makes the cost of power produced by an electric motor—if computed by the consumption of zinc in a battery—about sixty times as great as that of an equal power produced by a steam-engine consuming coal. He concludes that "it would be far more economical to burn zinc under a boiler and to use it for generating steam power than to consume zinc in a battery for generating electromagnetical power."

In the discussion which followed, several men of distinction took part. Professor William Thomson, of Glasgow (Lord Kelvin), wrote, referring to the results of Joule and Scoresby: "These facts were of the highest importance in estimating the applicability of electromagnetism, as a motive power, in practice; and, indeed, the researches alluded to rendered the theory of the duty of electromagnetic engines as complete as that of the duty of waterwheels was generally admitted to be. Among other conclusions which might be drawn from these experiments was this: that, until some mode of producing electricity as many times cheaper than that of an ordinary galvanic battery as coal was cheaper than zinc, electromagnetic engines could not supersede the steam-engine." Mr. W. R. Grove (Lord Justice Sir William Grove) remarked that a practical application of the science appeared to be still distant. The great desideratum, in his opinion, was not so much improvement in the machine as in the prime mover, the battery, which was the source of power. At present the only available use for this power must be confined to special purposes where the danger of steam and the creation of vapour were sought to be avoided, or where economy of space was a great consideration. Professor Tyndall agreed with the last speaker, but suggested that there might be some way of mitigating the apparent diminution of power due to the induction of opposing electromotive forces in the machine itself. Mr. C. Cowper spoke of some experiments, made by himself and Mr. E. A. Cowper, showing the advantage gained by properly laminating the iron cores used in the motor. He put the cost of electric power at £4 per horse-power per hour. He deprecated building electric motors with reciprocating movements and cranks; described the use of silver commutators; and mentioned the need of adjusting the lead given to the contacts. There was, he said, no reason to suppose that electric motors could be made as light as steam-engines. Even in the case of small motors of one-tenth or one-hundredth of a horse-power, for light work, where the cost of power was of small consequence, a boy or a man turning a winch would probably furnish power at a cheaper rate. Mr. Alfred Smee agreed that the cost would be enormous for heavy work. Although motive power could not at present be produced at the same expense on a large scale by the battery as by coal, still they were enabled readily to apply the power at any distance from its source; the telegraph might be regarded as an application of motive power transmitted by electricity. Mr. G. P. Bidder considered that there had been a lamentable waste of ingenuity in attempting to bring electromagnetism into use on a large scale. Mr. Joule wrote to say that it was to be regretted that in France the delusion as to the possibility of electromagnetic engines superseding steam still prevailed. He pointed out, as a result of his calorimeter experiments, that if it were possible so to make the electric engine work as to

reduce the amount to a small fraction of the strength which it had when the engine was standing still, nearly the whole of the heat (energy) due to the chemical action of the battery might be evolved as work. The less the heat evolved, as heat, in the battery, the more perfect the economy of the engine. It was the lower intensity of chemical action of zinc as compared with carbon, and the relative cost of zinc and coal, which decided so completely in favour of the steam-engine. Mr. Hunt, replying to the speakers in the discussion, said that his endeavour had been to show that the impossibility of employing electromagnetism as a motive power lay with the present voltaic battery. Before a steam-engine could be considered, the boiler and furnace must be considered. So, likewise, must the battery if electric power were to become economical. Then the President, Mr. Robert Stephenson, wound up the discussion by remarking that there could be no doubt that the application of voltaic electricity, in whatever shape it might be developed, was entirely out of the question, commercially speaking. The mechanical application seemed to involve almost insuperable difficulties. The force exhibited by electromagnetism, though very great, extended through so small a space as to be practically useless. A powerful magnet might be compared to a steam-engine with an enormous piston, but with exceedingly short stroke; an arrangement well known to be very undesirable.

In short, the most eminent engineers in 1857 one and all condemned the idea of electric motive power as unpractical and commercially impossible. Even Faraday, in his lecture on "Mental Education" in 1854, had set down the magneto-elecric engine along with mesmerism, homœopathy, odylism, the caloric engine, the electric light, the sympathetic compass, and perpetual motion as coming in different degrees amongst "subjects uniting more or less of the most sure and valuable investigations of science with the most imaginary and unprofitable speculation, that are continually passing through their various phases of intellectual, experimental, or commercial development, some to be established, some to disappear, and some to recur again and again, like ill weeds that cannot be extirpated, yet can be cultivated to no result as wholesome food for the mind."

Fifty Years Later.

Fifty years have fled, and Hunt, Grove, Smee, Tyndall, Cowper, Joule, Bidder, and Stephenson have long passed away. Lord Kelvin remains the sole and honoured survivor of that remarkable symposium. But the electric motor is a gigantic practical success, and the electric motor industry has become a very large one, employing thousands of hands. Hundreds of factories have discarded their steam-engines to adopt electric-motor driving. All travelling cranes, nearly all tramcars, are driven by electric motors. In the navy and in much of the merchant service the donkey-engines have been replaced by electric motors. Electric motors of all sizes and outputs, from one-twentieth of a horse-power to 8,000 horse power, are in commercial use. One may well ask: What has wrought this astonishing revolution in the face of the unanimous verdict of the engineers of 1857?

The answer may be given in terms of the action and reaction of pure and applied science. Pure science furnished a discovery; industrial applications forced its development; that development demanded further abstract investigation, which in turn brought about new applications. It was beyond all question the development of the dynamo for the purposes of electrotyping and electric light which brought about the commercial advent of the electric motor. For about that very time Holmes and Siemens and Wilde and Wheatstone were at work developing Faraday's magneto-electric apparatus into an apparatus of more practical shape; and the electric lighthouse lamp was becoming a reality, which Faraday lived to see before his death in 1867. That eventful year witnessed the introduction of the more powerful type of generator which excited its own magnets. And even before that date a young Italian had made a pronouncement which, though it was lost sight of for a time, was none the less of importance. Antonio Pacinotti in 1864 described a machine of his own devising, having a specially wound revolving ring-magnet placed between the poles of a stationary magnet, which, while it would serve as an admirable generator of electric currents if mechanically driven, would also serve as an excellent electric motor if supplied with electric currents from a battery. He thereupon laid down the principle of reversibility of action, a principle more or less dimly foreseen by others, but never before so clearly enunciated as by him. And so it turned out in the years from 1860 to 1880, when the commercial dynamo was being perfected by Gramme, Wilde, Siemens, Crompton, and others, that the machines designed specially to be good and economical generators of currents proved themselves to be far better and more efficient motors than any of the earlier machines which has been devised specially to work as electro-magnetic engines. Moreover, with the perfection of the dynamo came that cheap source of electric currents wnich was destined to supersede the battery. That a dynamo driven by a steam-engine furnishing currents on a large scale should be a more economical source of current than a battery in which zinc was consumed, does not appear to have ever occurred to the engineers who, in 1857, discussed the feasibility of electric motive power. Indeed, had any of them thought of it, they would have condemned the suggestion as chimerical. There was a notion abroad—and it persisted into the eighties—that no electric motor could possibly have an efficiency higher than 50 per cent. This notion, based on an erroneous understanding of the theoretical investigations of Jacobi, certainly delayed the progress of events. Yet the clearest heads

of the time understood the matter more truly. The true law of efficiency was succinctly stated by Lord Kelvin in 1851, and was recognised by Joule in a paper written about the same date. In 1877 Mascart pointed out how the efficiency of a given magneto-electric machine rises with its speed up to a limiting value. In 1879 Lord Kelvin and Sir William Siemens gave evidence before a Parliamentary Committee as to the possible high efficiency of an electric transmission of power; and in August of the same year, at the British Association meeting at Sheffield, the essential theory of the efficiency of electric motors was well and admirably put in a lecture by Professor Ayrton. In 1882 the present author designed, in illustration of the theory, a graphic construction, which has been ever since in general use to make the principle plain. The counter-electromotive force generated by the motor when running, which Hunt and Tyndall deplored as a defect, is the very thing which enables the motor to appropriate and convert the energy of the battery. Its amount relatively to the battery's own electromotive force is the measure of the degree to which the energy which would otherwise be wasted as heat is utilised as power. Pure science stepped in, then, to confirm the possibility of a high efficiency in the electric motor *per se*. But pure science was also brought into service in another way. An old and erroneous notion, which even now is not quite dead, was abroad to the effect that the best way of arranging a battery was so to group its component cells that its internal resistance should be equal to the resistance of the rest of the circuit. If this were true, then no battery could ever have an efficiency of more than 50 per cent. It was supposed in many quarters that this misleading rule was applicable also to the dynamo. The dynamo makers discovered for themselves the fallacy of this idea, and strove to reduce the internal resistance of the armatures of their machines to a minimum. Then the genius of the lamented John Hopkinson led him to apply to the design of the magnetic structure of the dynamo abstract principles upon which a rational proportioning of the iron and copper could result. A similar investigation was independently made by Gisbert Kapp, and between these accomplished engineers the foundations of dynamo design was set upon a scientific basis. To the perfection of the design the magnetic studies of our ex-President, Professor Ewing, contributed a notable part, since they furnished a basis for calculating out the inevitable losses of energy in armature cores by hysteresis and parasitic currents in the iron when subjected to recurring cycles of magnetisation. Able constructive engineers, Brown, Mordey, Crompton, and Kapp, perfected the structural development, and the dynamo within four or five years became, within its class, a far more highly efficient machine than any steam-engine. And as by the principle of reversibility every dynamo is also capable of acting as a motor, the perfection of the dynamo implied the perfection, both scientific and commercial, of the motor also. The solution in the eighties of the problem how to make a dynamo to deliver current at a constant voltage when driven at a constant speed, found its counterpart in the solution by Ayrton and Perry of the corresponding problem how to make a motor which would run at constant speed when supplied with current at a constant voltage. Both solutions depend upon the adoption of a suitable compound winding of the field magnets.

A little later alternating currents claimed the attention of engineers; and the alternating current generator, or "alternator," was developed to a high degree of perfection. To perfect a motor for alternating currents was not so simple a matter. But again pure science stepped in, in the suggestion by Galileo Ferraris of the extremely beautiful theorem of the rotatory magnetic field, due to the combination of two alternating magnetic fields equal in amplitude, identical in frequency and in quadrature in space, but differing from each other by a quarter-period in phase. To develop on this principle a commercial motor required the ingenuity of Tesla and the engineering skill of Dobrowolsky and of Brown; and so the three-phase induction motor, that triumph of applied science, came to perfection. Ever since 1891, when at the Frankfort Exhibition there was shown the *tour de force* of transmitting 100 horse-power to a distance of 100 miles with an inclusive efficiency of 73 per cent., the commercial possibility of the electric transmission of power on a large scale was assured. The modern developments of this branch of engineering and the erection of great power-Stations for the economic distribution of electric power generated by large steam plant or by water-turbines are known to all engineers. The history of the electric motor is probably without parallel in the lessons it affords of the commercial and industrial importance of science.

But the query naturally rises: If a steam-engine is still needed to drive the generator that furnishes the electric current to drive the motors, where does the economy come in? Why not use small steam-engines, and get rid of all intervening electric appliances? The answer, as every engineer knows, lies in the much higher efficiency of large steam-engines than of small ones. A single steam-engine of 1,000 horse-power will use many times less steam and coal than a thousand little steam-engines of 1 horse-power each, particularly if each little steam-engine requires its own little boiler. The little electric motor may be designed, on the other hand, to have almost as high an efficiency as the large motor. And while the loss of energy due to condensation in long steam-pipes is most serious, the loss of energy due to transmission of electric current in mains of equal length is practically negligible. This is the abundant justification of the electric distribution of power from single generating centres to numerous electric motors placed in the positions where they are wanted to work.

BRITISH TRADE UNION STATISTICS.

The fifteenth Report by the Chief Labour Correspondent of the Board of Trade on Trade Unions in 1902-04* gives, in addition to the detailed figures as to membership during 1904, comparative statistics between 1895-94. The report sets out a number of interesting facts and figures.

The number of separate workman's Trade Unions known to the Department as being in existence at the end of 1904 was 1,148, with a total membership of 1,866,755. In the three years of declining employment, 1902-04, there has been, as in previous periods of depression, a falling off in the membership of many Trade Unions. The total decline is from 1,940,874 at the end of 1901 (when the numbers were the highest recorded) to 1,866,755 at the end of 1904, a fall of 74,119 or 3·8 per cent. The total number of trade unionists remained, however, higher than at the end of 1899, and much higher than during the period 1892-98, the earliest years for which comparative figures are available. The decline was not so marked in the larger as in the smaller unions. The labourers' unions suffered most, trade unions of builders' and general labourers losing in the three years 30,000 members, or no less than 19·4 per cent. of their membership in 1901. The mining and quarrying group also lost nearly 30,000, but this represents a fall of only 5·5 per cent. of the membership of the group. These two groups account for more than three-fourths of the total. Considerable losses were also sustained by the tailoring group (18 per cent.) and the transport group (7 per cent.). On the other hand a comparatively large increase in trade union membership took place during 1902-04 in the small groups of employees of Public Authorities, which gained 12,000 (or 23·6 per cent.), and of shop assistants, which increased from 19,000 to 30,000, a gain of 60·0 per cent. A gain of 7·1 per cent. by the printing and kindred trades group has also to be recorded.

Taking the hundred principal unions only it is interesting to note an increase in membership during the ten years under review from 907,496 to 1,127,529. The income per member has been a varying quantity, ranging from 33s. 11¾d. in 1895 to 37s. 4¼d. in 1897, falling to 33s. in 1899, and since rising to 37s. 2½d. The expenditure per member has been a varying quantity, notable years being in 1897, 36s. 0¼d.; in 1899, 22s. 8d.; and in 1904, 36s. 2¾d. The value of the accumulated funds per member were 37s. 8¾d. in 1895, 44s. 11d. in 1896, fell to 42s. 0¼d. in 1897 (being depleted by disputes), and have since risen to 81s. 10½d. The rate of increase in funds is slackening appreciably.

During the ten years under review £16,060,000 has been spent by the 100 principal unions. Of this amount about £2,343,000, or 14·6 per cent. of the total, has been spent on dispute pay, £3,608,000, or 22·5 per cent., on unemployed benefits, and £6,658,000, or 41·4 per cent., on other benefits (principally sick and accident, superannuation, and funeral benefits), the remaining £3,451,000, or 21·5 per cent., having been used in the payment of working and miscellaneous expenses.

The proportion of the total expenditure accounted for by disputes in the last four years has fallen considerably. In 1904 a smaller proportion was spent on dispute pay, and a larger proportion on unemployed benefit than in any other year. In the first five years the proportion spent on unemployed benefit steadily fell with the improvement in employment. In the remaining five years, 1900-04, owing to the decline in employment, the proportion gradually increased until in 1904 it was higher than in 1895, and more than twice as great as in 1899 (a year of exceptionally good employment) amounting to 31·7 per cent. of the total expenditure, whereas 6·2 per cent. was expended on dispute benefit. The proportionate extent of working and miscellaneous expenditure has fallen from 25·8 per cent. in 1899 to 22·4 per cent. in 1894.

Passing next to the items comprising the detailed report, it is stated that "Concurrently with the general increase in unemployment during the period 1902-4, and in agreement with the experience of previous similar periods, there has been a decline in the number of members of trade unions. The total membership, which had reached 1,940,874 in 1901, fell in each of the years 1902-4, and at the end of the period was 1,866,755. It still remained, however, higher than at the end of 1899, and was much higher than at the end of any year during the period 1892-98, the earliest years for which comparative figures are available."

As compared with 1901, except in the textile trades, which on the whole show little change, all the main groups of trades have sustained a decline in membership. In the metal, engineering, and ship building trades the loss amounts to only 0·8 per cent., but in the mining and quarrying group it is 5·5, in the transport group 7·0, in the building group 9·6, and in the clothing group 11·0 per cent. In the building trades the loss was felt chiefly by the labourers' unions, their membership declining by one-third. The other building trade unions lost 5 per cent., notwithstanding a notable increase of 3,745 in the membership of the Amalgamated Society of Carpenters and Joiners. In the clothing trades the tailors' unions were the heaviest losers, their membership falling 18 per cent. The other unions in the clothing trades lost 7 per cent.

Generally speaking, the unions which have suffered least in loss of members are those paying the most varied and liberal scales of benefits.

Some interesting figures relating to the manner in which female workers support the trade union movement are given. While, during the years 1896-1904, the male membership of all trade unions has risen from 1,386,709 to

---

* No. Cd. 2838. Price 1s. 2d., published by Wyman and Sons, Ltd., Fetter-lane, E.C.

1,741,661, the female membership has remained almost stationary at about 120,000.

As regards individual trades, the only group worthy of note as having shown a substantial rise in membership is that of the shop assistants' unions, whose female membership rose, without a break, from 327 in 1896, to 1,609 in 1901, and 3,739 in 1904.

Nearly 90 per cent. of female members of trade unions are found in the textile trades, cotton weaving accounting for 60 per cent., cotton preparing for 18 per cent., and linen and jute manufacture for 8 per cent.

Another section deals with the income of the principal unions, in which it is shown that the average receipts per head of the principal unions during the ten years ending 1904, were as follows:—

	£	s.	d.
Building	1	16	7¼
Mining and Quarrying	1	2	6¼
Metal, Engineering, and Shipbuilding	3	5	11½
Textile	1	12	1
Clothing	1	4	11¼
Transport	1	0	8
Other unions	1	5	2¼

The figures relating to the metal, engineering, and shipbuilding trades are inflated by the dispute of 1897-98. Excluding these years, the income for the remaining eight was £3 2s. 8¾d.

Percentage expenditure for all the unions has already been referred to. Specific figures are given of groups of trades. As has been said, dispute benefits have been greatly reduced, but unemployed benefits have risen considerably. Sick and accident payments have also risen, the cost under the latter head having risen from 5s. 2½d. per member of the 100 principal unions in 1898 to 6s. 9¾d. per member in 1904.

Another valuable piece of work, namely, that of superannuation benefit, is unfortunately paid by a comparatively small number of the 100 unions, principally in the engineering, shipbuilding, building, and printing trades. None of the miners', weavers' and labourers' unions pay this benefit; but in the case of the miners it is provided by Miners' Permanent Relief Societies. The form taken by superannuation benefit is in nearly all cases that of a weekly payment, such payments varying greatly in amount. In some cases no more than 2s. a week is paid; in a few instances the amount reaches 12s. per week. More commonly, however, it lies between 5s. and 10s. A point of interest is that the fact that a member of a union paying superannuation benefit has arrived at a certain age, and has completed the prescribed period of membership does not necessarily entitle him to the benefit. The rules of some of the unions state that, in order to be eligible for the benefit, a member must be unable to work at his trade, or at any rate be unable to earn full wages. Expenditure upon this heading is becoming annually a more important matter. Costing 6s. 2¾d. per member of these unions in 1898, by 1904 this sum had risen to 9s. 7¼d., or over 50 per cent.

Another section of the detailed report deals with the accumulated reserve funds of the 20 chief unions which in 1894 possessed funds amounting to £50,000 and upwards. The funds of these twenty unions amounted at the end of 1904 to £3,628,243, or 79 per cent. of the funds of the 100 principal unions. Only two of the twenty show a decrease in funds per member as compared with 1895, and most of them show a large increase, the Derbyshire and Nottinghamshire miners having gained over £5 per member, the Ironmoulders of Scotland and the Patternmakers over £6, and the Cotton Spinners over £13.

The disposition of the funds of the 100 principal unions, which amount to £4,616,230, consists of £1,943,786 deposited in banks, cash in hand and office furniture (this item being "a very small proportion of the total amount"), and the following chief investment. —Corporations and public trusts £1,361,167, railways £198,655, freehold and leasehold property £238,933, and mortgages £442,880.

Federations of Trade Unions and Trades Councils are described together with the scope of their activities. The remainder of the book is given to diagrams illustrative of membership, expenses, income, funds, &c., and to a most exhaustive series of tables relating to the number and membership of all trade unions, to the accounts of the 100 principal trade unions, and to statistics respecting federations and trades councils. The interest of these is general rather than precise. Reference to them is, therefore, unnecessary in this abstract.

IRON ORE SUPPLIES.*

Of all the problems with which the practical geologist has to deal, none is of greater importance at the present time than the discovery of fresh sources of iron ore supply. Every inhabitant of the United Kingdom, of the United States, and of Germany requires annually about a quarter of a ton of the iron of which the world last year produced 60,000,000 tons, the result of the smelting of over 120,000,000 tons of ore. Year by year the production and consumption are increasing, and many of the deposits of the richer ores are showing signs of depletion. The question of ascertaining how the demand for the vast supplies of iron ore that will in the future be needed will be met, calls therefore, for very serious consideration; and a few statistical notes may be useful as a contribution to a discussion of the subject.

During the past half century the development of the iron industry has been remarkable. In 1864, Mr. J. K. Blackwell showed that the world's production of pig-iron did not exceed 6,000,000 tons, of which the United Kingdom produced 50 per cent., France and the United States each 12½ per cent., and Germany 6 per cent. In 1905 the world's production

* Paper read by Bennett H. Brough, Assoc.R.S.M., F.G.S., F.I.C., before Section C of the British Association, at Leicester.

had attained the enormous total of 56,000,000 tons, of which the United States produced 42·7 per cent., Germany and Luxemburg 20 per cent., the United Kingdom, 17·6 per cent., and France 5·5 per cent.

In Great Britain the principal iron-ore producing districts are Cleveland, in North Yorkshire, which in 1905 yielded 41·0 per cent. of the total output of the kingdom; Lincolnshire (14·8 per cent.), Northamptonshire (13·9 per cent.), and Leicestershire (4·7 per cent.), together yielding 33·4 per cent. of the total output; Cumberland (8·6 per cent.), and North Lancashire (2·7 per cent.), Staffordshire (6·1 per cent.), and Scotland (5·7 per cent.). The Cleveland iron ore occurs in a 10-foot bed in the middle lias, and contains about 30 per cent of iron. It is worked by underground mining. In Lincolnshire, Northamptonshire, and Leicestershire the brown iron-ore beds form part of the Inferior Oolite, and contain about 33 per cent. of iron, the workings being mostly opencast. In Cumberland and North Lancashire the red hæmatite occurs in irregular masses in carboniferous limestone. It contains more than 50 per cent. of iron, and is worked by underground mining. The ironstone in Staffordshire and in Scotland is mostly obtained from mines that also produce coal.

Such, in brief, are the home deposits from which the British supply of 14,590,703 tons of iron ore, valued at £3,482,184 was obtained in 1905. Even that enormous output did not meet the consumption, and 7,344,786 tons were imported. Of that amount, 78·5 per cent. was brought from Spain, 5·4 per cent. from Norway, 4·2 per cent. from Greece, 4·0 per cent. from Algeria, 2·6 per cent. from France, 2·6 per cent. from Sweden, 1·5 per cent. from Russia, and smaller quantities from Turkey, Germany, islands in the Pacific, Belgium, Newfoundland, India, Australia, Italy (Elba), Persia, Portugal, and other countries. In fact, the world is being ransacked for fresh iron-ore fields to supply ores for the British blast-furnaces. The port at which most of the ore was delivered was Middlesbrough (1,789,639 tons), then followed Glasgow with 1,042,179 tons, and then Cardiff with 865,462 tons.

While it is probable that the British ore fields will be exhausted in a century or two, the outlook in other countries is similar. This is borne out by data relative to the available iron ore supplies of the world which have been collected by Törnebohm for the Swedish Parliament, and, although largely conjectural, these figures are of great interest.

In the United States the iron-ore production in 1905 exceeded 42½ million tons, the highest output ever recorded, the ore containing more iron than the ores raised in Germany, in the United Kingdom, and in Spain combined. The bulk of the production was obtained in the Lake Superior region, where the five iron-ore belts, or ranges (Marquette, Menominee, Gogebic, Vermilion, and Mesaba), beds of pre-Silurian Age, have furnished since the beginning of regular mining over 300,000,000 tons of iron ore. The average percentage of iron in the ore is 55, the 60 per cent. ores produced ten years ago having been exhausted by wasteful mining methods. The amount of ore still available in the United States is estimated by Törnebohm at 1,100,000,000 tons.

In Germany and Luxemburg two-thirds of the iron ore raised (23½ million tons in 1905) is derived from the so-called minetic beds of Jurassic brown iron ore. The seams yield, on an average, 36 per cent. of iron, and 1·7 per cent. of phosphoric acid. Owing to the high percentage of phosphorus the ore was of little value until 1879, when the basic method of making steel was brought into practical use by Thomas and Gilchrist. The amount of ore still available in Germany is estimated at 2,200,000,000 tons.

In Spain the chief deposits are near Bilbao; the ores, which are of great purity, occurring in beds of Cretaceous age. Up to the present time the Bilbao district has yielded about 115,000,000 tons of ore, and for many years pessimistic estimates have been made of the quantity of ore remaining. Twenty years ago it was thought that by the year 1900 there would be no ore left. Nevertheless, in that year Bilbao exported 5,000,000 tons of ore, and Don Julio de Lazurtegui, the most competent authority, estimated that there were still over 57,000,000 tons left. The richest red hæmatite ores are, it is true, now exhausted, and brown hæmatites and spathic ores have taken their place, with the result that more attention has to be paid to calcination and to the washing of ores to enable them to satisfy market requirements. Törnebohm's estimate of the quantity of ore still available in Spain is 500,000 tons.

In Sweden, deposits of magnetite of great purity occurring in gneiss supply material for the charcoal blast furnaces, and ores rich in phosphorus are mined for export at Grängesburg, in central Sweden, and within the Arctic Circle at Gellivare, Kirunavaara, and Luossavara, where there are ample supplies to meet the increased demand that is likely to arise. These deposits have been described in great detail by Dr. Stutzer in a paper submitted at the last meeting of the Iron and Steel Institute. The export of iron ore from Sweden in 1905 amounted to 3½ million tons. In Northern Norway important discoveries of similar iron ore deposits have of late been made. The amount of ore still available in Sweden is estimated at 1,200,000,000 tons.

In France the most important deposits are the beds of oolitic iron ore in the department of the Meurthe-et-Moselle; and in Russia the greater portion of the iron ore produced is obtained from the Ural region, where, on the western side, the ores are chiefly limonite and spathic ores of a stratified character, and, on the east, masses of magnetite associated with igneous rocks. The amount of ore available in France is estimated at £1,500,000,000 tons, and in Russia at the same amount. The available resources of other countries are estimated by Törnebohm at 1,200,000,000 tons. Including 1,000,0 0,000 tons for Great Britain, he estimates

the known available resources of the world at 10,000,000,000 tons.

The outlook for the British industry is not altogether a depressing one, for, whilst the rich ores of Bilbao and Elba are becoming scarce, there are still vast quantities of ore available in the north of Scandinavia, in the south of Spain, in Algeria, Canada, Cuba, Brazil, Venezuela, Chili, India, China (notably in the Shansi district), Australia, and South Africa. The high cost of carriage is, of course, an important factor; but the great economies which have, and will be, effected in transport will reduce this item. The future of the home demand is likely to be affected by the development of the basic open-hearth process of steel-making which enables phosphoric ores to be utilised. In the course of time such phosphoric ores will doubtless occupy a very prominent place in the manufacture of high-class steel. The development of magnetic concentration and of the briquetting of pulverulent ores for furnace use will render possible greater utilisation of poorer ores, while the development of the electric furnace will doubtless render it possible to utilise black sands and other titaniferous iron ores which, although met with in abundance, cannot at present be treated profitably in the blast-furnace. There need therefore be no immediate anxiety regarding the supply of the more impure ores, the application of which cannot fail rapidly to increase.

THE AGRICULTURAL INDUSTRIES OF THE PHILIPPINES.

The most important product of the Philippine Islands at present is the fibre known throughout the civilised world as Manila hemp. It is not a hemp in the ordinary acceptation of the term, as the fibre is produced from the leaf of a large plant similar in appearance to the banana plant or tree, while in most cases hemp is the fibre extracted from the inner bark of the stem of a plant. Manila hemp, or "abaca" as it is termed, is apparently a strictly Philippine product, and holds a high rank among the fibres of the world for manufacturing purposes. Abaca has been introduced from the Philippines into India, Borneo, the West Indies, and elsewhere, but apparently without success, and this failure to produce it elsewhere adds to the importance of the industry in the Philippines and to its probable development. According to the Fibre Expert of the Philippine Bureau of Agriculture, the opportunities for increasing its production are almost unlimited. The production of hemp has grown rapidly in recent years, the exportation having been, in 1880, but 51,000 tons; in 1890, 50,000 tons; in 1900, 89,000 tons; and in 1905, 128,000 tons, while the value has increased from £1,000,000, in 1880, to £4,400,000, in 1905. With the adaptation of machinery to the preparation of hemp for marketing, the area cultivated will doubtless greatly increase, and as the world is constantly demanding all the hemp which the Philippines can at present offer, there is reason to believe that this industry may be greatly developed, and the exports of this article may, it is said, alone amount to £20,000,000 in value.

Another plant of the hemp family which is likely to become an important factor in the wealth production of the Philippines is maguey or sisal. Sisal ranks next to Manila hemp among the coarse and strong fibres needed for the manufacture of ropes, binding twine, &c. So important has it become in the manufacturing industries of the world that its importation into the United States alone has grown from £700,000 in 1896 to £3,050,000 in 1906. At present nearly all the sisal imported into the United States is brought from Mexico, where the production has, within a comparatively recent period, made Yucatan one of the richest States in the Republic. While the plant was introduced many years ago, probably from Mexico, it is only during the last few years that planters in the Philippine Islands have devoted attention to its production and development, and therefore only recently that its value as a fibre plant, and prospective value to the commerce of the Philippines, have been realised. The machinery used for fibre extraction in the sisal regions of Mexico applies, it is said, with equal satisfaction to the maguey plant in the Philippines. The growth of the maguey industry in the Philippine Islands during the past four years indicates that it will, at no distant date, become one of the important agricultural products. Maguey has one advantage over abaca in that, in its cultivation, it cannot be blown down or uprooted by violent winds. Another fibre in the cultivation of which experiments have been made is jute, but so far the experiments have not proved very satisfactory, and the world is at present chiefly dependent upon India for jute.

Sugar is perhaps the next important article after hemp in the production of the islands. The production of sugar in the Philippines has never at its very highest figure exceeded 350,000 tons, nor is the present production for export more than 100,000 tons annually. The United States demands annually 2,000,000 tons, and the whole world demands over 12,000,000, and there is good reason to believe that the sugar exports of the Philippines, which in 1905 were but one million sterling in value, may far exceed that figure with the introduction of modern machinery, the enlargement of the area which sugar-producing estates may control, and the bringing into cultivation of large sugar areas not now utilised. In the period from 1860 to 1890, the share which sugar formed of the total exportation ranged from 25 to 50 per cent., and in two or three years exceeded 50 per cent. of the total exports, while in the period since 1900 it has formed only from 10 to 15 per cent. of the total exports, and the quantity exported has fallen from about 700,000,000 lbs. in 1895, to 239,000,000 lbs. in 1905. Tobacco is classed as the third agricultural product of the islands in point of commercial importance. Originally introduced from America into the

Philippines by Spanish missionaries in the latter part of the sixteenth century, its cultivation has extended throughout the group of islands, but it is especially grown in the northern part of the most northerly island, Luzon. The home consumption is large, and in consequence the quantity available for exportation is comparatively small, having at no time in the last thirty years reached as much as £600,000 in value. Most of the tobacco exported goes in the natural form. The cocoanut and its products now form a considerable and rapidly-increasing percentage of the exports from the Philippine Islands. Copra, or the dried meal of the cocoanut, now ranks third in the total exports of the islands. In 1905 it amounted in value to £650,000, and in the fiscal year 1906 to £809,000. This large growth in the exportation of copra is due to the developments of recent years by which the nuts may be readily transported in a dried or desiccated state to those countries which have facilities for utilising the oil for manufacturing purposes. From it cocoanut oil and cocoa butter are manufactured, and the residuum, after expression of the oil, is an excellent food for stock, with many of the nutritive properties of cotton seed cake. The *Phillipine Census*, discussing this industry, says that copra is a comparatively new product and bids fair to become of much greater relative importance in the commerce of the Philippines than at present. In view of the increasing demand for cocoanut products this industry, when prosecuted upon a large scale, promises to be for many years one of the most profitable enterprises which command the attention of the Philippine planter, while the area available for production of cocoanuts is very large.

Coffee is not at present a very large item in the export trade of the Philippine Islands, or indeed of great importance from the point of view of production. Prior to 1890 it was a remunerative product of certain provinces, and constituted a source of considerable wealth in the districts in which it was cultivated. In 1890 coffee ranked fourth in order of magnitude in the export trade of the islands, and did not fall below tobacco in the value of its exports, having been in 1890 7·4 per cent., and in 1889 7·1 per cent. of the total exports of the islands. Subsequent to 1890, however, the devastation of the coffee plantations by insects and disease caused a rapid diminution in the quantity produced and exported, but there is reason to believe that the same energy and scientific methods applied by the Dutch in Java to the protection of their coffee from insects and disease, and a re-establishment of their coffee area might bring about a large coffee production in the Philippine Islands. The quality of the Philippine coffee is said to be especially fine, comparing favourably with that of the comparatively near-by island of Java. Coffee was brought to the islands by Spanish missionaries during the latter part of the eighteenth century, and its systematic cultivation commenced early in the nineteenth century. Cacao is another article in which the production and commerce of the Philippine Islands may be largely developed. Cacao cultivation exists in nearly all parts of the archipelago, and with the growing demand in all parts of the world for this product, it seems probable that it may become an important wealth producer in the islands, and add materially to their commerce. The cultivation of the cacao plant, from the seed of which chocolate is obtained, is carried on in various parts of the slands, and in spite of crude and wasteful methods has proved a highly profitable and promising branch of agriculture. No appreciable commercial surplus of the product has yet been grown, practically the entire output being consumed in the islands, but the perfect adaptability of many districts to its successful cultivation, the superior quality of the chocolate produced from it, and the certainty of remunerative returns from the industry, lead to the belief that this may become a profitable branch of agriculture, and will hereafter be carried on more extensively, and add materially to the value of Philippine exports.

CAUSES OF STRENGTH IN WHEATEN FLOUR.*

The Home-grown Wheat Committee of the National Association of British and Irish Millers has for several years been engaged in producing wheats in England which shall yield maximum crops of grain and straw, the wheat to be equal in strength, and therefore in commercial value, to the best imported varieties.

The field of inquiry has been a wide one, and among other things the Committee has sought to ascertain "the ultimate cause of strength in wheat, the nature and source of those constituents which confer on some varieties of wheat the inherent quality of strength, and the power of transmitting it to succeeding generations." It has been proved that though climate and soil influence quality they are not the determining factors in the production of strength, for though the strongest wheats are ordinarily produced in districts where the winters are cold, the summers hot, and the summer rainfall high, certain varieties possess and retain the inherent quality of strength when grown in England. Manuring or early cutting at harvest time has no beneficial effect on quality. Quick growth or rapid maturation is not correlated with strength, nor does the percentage of natural moisture in well-harvested wheat indicate it; indeed in certain cases the addition of water to wheat materially increases its effective baking strength.

The term "strength" has been loosely applied to cover several characteristics. In the view of the Committee it should not be measured by the quantity of water required to make doughs of a standard consistency, nor by the quantity of bread produced per sack of flour used, nor by the way a flour behaves in the

* Abstract of paper read by Mr. A. E. Humphries before Section B of the British Association, at Leicester.

dough, but by its capacity for making big, shapely, and therefore well aerated loaves. This definition covers two characteristics: one, a flour's capacity for making gas in yeast fermentation; the other, its capacity when made into dough for retaining the gas so generated.

The gas-making power will depend largely on the percentage of natural sugar any given wheat contains and its diastatic capacity. These characteristics vary substantially in different wheats. The baker can, and does, influence the quantity of gas generated in baking. The retention of gas when made involves complex problems.

The percentage of total nitrogen, gluten, gliadin, and amyloids do not correctly indicate the relative strengths of various flours. The theory of strength depends on a correct ratio between gliadin and glutenin is untenable. Professor Wood's suggestion that the gas-retaining power of a dough depends on its ratio of protein to salts is worthy of the closest attention in view of the fact that the physical, as distinct from the chemical, properties of proteins are profoundly affected by small quantities of acids, alkalis, and salts.

FRENCH SILK SCHOOLS.

The Ecole Supérieur de Commerce in Lyons, the centre of the French silk industry, receives pupils from foreign countries, and teaches them the entire silk business, from the raising of the worm, to making the designs, weaving the silk and putting it upon the market. While a pupil is at this school learning to make silk, he can also acquire a thorough knowledge of the French language. A two years' course of study includes loom and weaving instruction, commercial law, political economy, book-keeping, and modern languages, the charge for foreigners being £40 per annum. At the end of the two years' course, the pupil never has any difficulty in obtaining a situation in one of the silk houses of Lyons. The two silk schools in Lyons are expected to supply young men for the silk houses in that city and in others also. The second school in Lyons, teaching the silk business, is the Ecole Municipal de Tissage et de Broderie, which is owned by the city and is intended only for the children of the inhabitants. It is free, with the exception of a registration fee of two shillings and sixpence. The American Consul at Lyons says that foreigners, however, are admitted on equal terms with the natives. It is not known how long this will be continued. It has been proposed to suspend their admission, but they continue to attend and enjoy all the advantages of the school for the sum of two shillings and sixpence for the two years. In each of these schools a young man has all the advantages of learning a good business, and at the same time the language and social habits and customs of the country.

HOME INDUSTRIES.

The Agricultural Returns. — The Preliminary Statement for 1907 has just been issued by the Board of Agriculture and Fisheries, and shows that the total acreage under wheat has again receded. For many years there was constant decline, but in 1905 there was marked expansion in the area under wheat cultivation. In 1904 it had fallen to 1,407,618, a much lower acreage than any since these statistics were first kept. Under the influence of better prices, 1905 saw a substantial increase to 1,836,598 acres, but last year the area under wheat fell away to 1,755,696, and this year it is only 1,625,488 acres, or, excepting the years 1903 and 1904, the lowest on record. Barley also shows a decrease, comparatively small, from 1,751,238 acres to 1,712,166 acres. Oats, beans, peas are all larger, and the total acreage under clover and rotation grasses has increased from 4,440,746 to 4,491,028 acres, whilst permanent grass has increased again from 17,244,734 acres to 17,278,243. It is satisfactory to find that the area under fruit continues to increase steadily if slowly. The improvement as between last year and this is as from 80,226 acres to 82,167 acres. Ten years ago the acreage under small fruit was only 70,245. As was anticipated, the disastrous results of last year have led to a further contraction of hop cultivation. In 1906, the area under this cultivation was only 46,722 acres, this year it has fallen to 44,938 acres. The probabilities point to further contraction in this cultivation, agriculturists being more and more disinclined to handle a crop where the risks are always very great and the lean years more frequent than the fat ones. On broad grounds this contraction is much to be regretted, for there is no crop grown that employs anything like as many hands. Turning to live stock, the preliminary statement shows that the number of horses used for agricultural purposes, and of unbroken horses, continues to decrease. In 1906 the number was 1,568,681, this year only 1,556,407. Ten years ago the figures were 2,069,880. Cattle too have fallen from 7,010,856 to 6,912,519. Ten years ago the figures were 11,004,973. Sheep, on the other hand, have recovered somewhat from 25,420,360 to 26,116,503, but here, again, as compared with earlier years, the figures show large decreases. It is the same with pigs. They have increased, as compared with 1906, from 2,323,461 to 2,636,808, but in 1897 they numbered 3,683,043, and in 1891, 4,272,700. If the total acreage under all crops and grass is taken, it amounted in 1906 to 32,266,755, and this year it is somewhat less, 32,244,110 acres.

The Wealth of the Kingdom.—The great and growing wealth of the United Kingdom is shown by the Income-tax records to be found in the Annual Report of the Commissioners of Inland Revenue issued a few days ago. The gross income from all classes of profits brought under the review of the department amounted in 1905-6 to £925,184,556.

These figures apply to not much more than one-ninth of the population. Year by year the aggregate increases by several millions. The income on which income-tax was received in 1905-6 amounted roughly to £636,000,000, and the actual sum received was £31,891,949, or a trifle over 5 per cent. In the eleven years 1896-97—1906-07 the net receipt of income-tax has almost doubled, increasing from £16,901,341 to £31,891,949, but, of course, the increased rate has a good deal to do with this growth, the income on which the tax was received having grown only from £503,664,630 to £636,000,000. It may be noticed that whilst the net receipt of the tax has in England increased from £14,715,755 to £28,024,957, and in Scotland from £1,519,336 to £2,687,957, in Ireland the increase is only from £665,950 to £999,246.

The Cotton Industry.—Notwithstanding a considerable number of new mills which have not yet got into working order, and which follow the great increase of mills during the last two or three years, other new mills are being put up and projected. As explained in a recent Note, the new mills at present being erected have been delayed owing to the inability of the machinists to deliver within contract time, or anywhere near it. The prospects of the American cotton crop remain uncertain, but good reports come from the Atlantic States and the Eastern Gulf region, and if the reports are less favourable from Tennessee, Mississippi, Louisiana, Texas, and the south-west generally, Manchester seems to be pretty well satisfied that the crop will be an average one, and the surplus carried on at the end of this season will be larger than last. Taking July the exports of cotton piece goods show about the same increase over those of 1906, as the exports of that year showed expansion over the same month of 1905, the figures being for 1905 510,440,000 yards, for 1906 573,527,800 yards, and for 1907 634,158,000 yards, but although the aggregate of the first seven months of the present year (3,769,999,000 yards) shows a considerable increase over the exports for the corresponding seven months of 1906 (3,690,231,400 yards), it is a good deal less than the increase in the same months of 1906 over those of 1905 (3,515,911,300 yards). The exports of bleached, printed, and coloured goods have been larger this year, but there has been a falling off in the exports of grey and unbleached calico. Exports of yarn also show a large increase. Taking the seven months, the exports of 1905 were 114,158,000 lbs.; of 1906, 122,452,200 lbs.; and of 1907, 135,874,100 lbs., the increase in 1907 over 1906 being considerably larger than those of 1906 over 1905. The exports to Germany account for much, indeed, almost all this year's increase, it being 12,000,000 lbs. more than in the same period of 1906. There are some grounds for fear that the relations of cotton masters and men may take an unfavourable turn after the holidays, but if this danger is averted, and the supplies of raw material come up to expectation, the Lancashire cotton industry is likely to enjoy a further period of prosperity. The past week was noticeable for the arrival at Liverpool of a consignment of over 1,050 bales of cotton from Nigeria. The cotton is said to be of useful quality, and to be excellently baled. The West Indies too are making some headway in the growth of cotton, and it is estimated the next year, 1907-8, will see shipments of cotton lint and seed from the islands of a value of a quarter of a million sterling.

The Shoe Industry.—For some time past the Leicester shoe industry has not been in a flourishing condition. More and more the large industrial villages of Leicestershire and Northampton have been making headway at the expense of the town. The invention of oil engines, and the adoption of up-to-date shoe machinery, have made this competition possible. The country factory has become almost as efficient as that of the town, and the town has to reckon with higher rents, heavier rates, higher wage bills. The result is that the town manufacturer is finding it increasingly difficult to quote successfully against his country rival. Within the past year many old-established Leicester firms have either retired from the business, or gone into the country, while firms owning both town and country factories are extending the latter rather than the former. The effect upon Leicester has been disastrous. There are many hundreds of empty houses in the town, and although there has been some improvement in the shoe trade, Leicester's rate of pauperism last month was exceeded (outside, however) only by Cardiff and the Potteries. Now war is threatened between masters and men. The two Leicester branches of the National Union of Shoe Operatives have given three months' notice to the Local Conciliation Board that they desire minimum wages of 32s. for men, and 21s. for women over 18, and that in view of the large number of men out of employment, they require the Board to discuss the question of abolishing overtime. At present pressmen and rough stuff cutters have a minimum of 26s., and other men 29s. per week. There is no minimum for women, but those who are 18 years of age or more earn from 12s. to 24s., according to the skill and the class of work on which they are engaged, the average being 14s. or 15s. It will be seen from these figures that the operatives demand a good deal, probably much more than they expect to get. The masters do not deny that it is a reasonable demand on the part of the men to require higher wages having regard to the rise in town rents, and the weeks in which there is no work to be had in the present state of things. Unfortunately, the profit of the Leicester manufacturer is now so narrow that he does not see his way to raise his wages bill. He would do it quickly enough if there was the prospect of corresponding advances being made throughout the trade, but there is not. There are said to be 400 non-federated firms through-

out the country who would not be bound by any agreement that might be made between the Leicester masters and men, and they employ over 50,000 people most of whom are unionists. This statement was made at the last annnal meeting of the Federation of Boot Manufacturers' Association in reporting on the union's proposal for a conference as to reducing the hours of work to forty-eight per week.

The State and Trade.—At the meeting of the Association of Chambers of Commerce which meets at Liverpool this month, the following resolution advocating the strengthening and consolidation of commercial organisation will be moved by the Birmingham delegates:—(1) The appointment of a Minister of Commerce of Cabinet rank; (2) the creation of an influential and thoroughly representative Advisory Board of Commerce; (3) the conferring of an official status upon the Chambers of Commerce; and (4) the provision of a complete system of intercommunication between the Chambers of Commerce and the Minister and his Advisory Board. The Prime Minister and the President of the Board of Trade will be asked to receive a deputation on the subject. Meantime, the Report of Sir Eldon Gorst and Mr. Llewellyn Smith on the System of British Commercial *Attachés* and Commercial Agents has been issued. It finds many defects in the present system. The expectation that British firms would utilise the services of the *attachés* for the purpose of conducting special inquiries at a distance has not been realised. The present arrangements for commercial agents are entirely provisional, and the framers of the Report can see no reason why their functions should not be equally well discharged by the Consular staff, strengthened where necessary for the purpose. The Report recommends that the existing commercial *attachés* residing in European capitals should have their head-quarters in London, and divide their time between special investigations abroad, particularly in districts of interest to British manufacturers, work in the Board of Trade, or the Commercial Department of the Foreign Office, and visits to the manufacturing districts in the United Kingdom.

CORRESPONDENCE.

IMPROVED METHODS OF DUST PREVENTION IN THE GRINDING TRADES.

The principle mentioned by Mr. Bennett in his communication upon grindstones, which appeared in your issue of August 30th, that the steel and stone dust fly from the wheels with considerable velocity, and that if they are to be arrested it must be by some obstacle placed in their path, and not by currents of air, was due to observations made by Dr. Whitelegge, the principal Inspector of Factories, and myself on a visit to Sheffield this spring. I cannot say how far this principle is a new one, but it is a valuable one as a starting point for the construction of hoods to grindstones. It should, however, not be pushed too far, for finer and lighter sorts of dust are impeded by the air in a ratio dependent on their degree of fineness, as has been demonstrated mathematically by the late Sir George Stokes (see p. 10, vol. ii. of his works). But with regard to steel and silica dust in the close vicinity of grindstones it is desirable to arrange hoods so as to intercept the flight of the particles, and it appears also probable, and is borne out by some experiments which we have made, that by a suitable arrangement of the hoods, the air flung off centrifugally by the grindstone as it rotates may be utilised to aid the blast. This principle, I believe, is not a new one, and, indeed, it is so obvious that it must have been thought of, but it would be very instructive if some of the firms engaged in the manufacture or use of grindstones would experiment in this direction.

H. CUNYNGHAME.

GENERAL NOTES.

BRITISH TRADE WITH SHANGHAI.—Conditions are changing in the business life of Shanghai, more rapidly perhaps than in any other part of the Far East. Continental and American firms are entering the field and pushing their wares with energy and aptitude. Large sums have recently been spent by Manchester firms in sending travellers to Shanghai, but they do not seem to make much headway. Commenting upon the position in his report upon the trade of Shanghai (Cd. 3283), Mr. Archibald Rose, of His Majesty's Consular Service, says that, in his opinion, young and energetic firms on the spot, who have a knowledge of their business and their customers, and who are willing to do pioneer work, are likely to prove most successful in meeting new demands and introducing new goods. The keen competition now springing up in Shanghai makes it necessary for the man on the spot to watch the markets and discover every possible opening for new products. "The first flush of Western education," writes Mr. Rose, "has given to the provincial populations a sudden desire for new things, and it has created a demand for which people are learning to cater. For the present such considerations may be of little interest to the wealthy piece-goods firms of Shanghai, who rely upon their old-established connections, and who are able to trust to their large wholesale transactions with the influential native merchants established here, who are moreover on firm ground, owing to their command of an international credit which still seems distant from the purely Chinese undertakings. At the same time there is in China a vast field of new activity for the British business man who is willing to work hard in understanding his subject."

CANTOR LECTURES.

GOLD MINING AND GOLD PRODUCTION.

BY PROF. JOHN WALTER GREGORY, D.Sc., F.R.S., F.G.S.

Lecture I.—Delivered January 28, 1907

I.—ALLUVIAL GOLD MINES.

Mining is the art of obtaining minerals and ores from the earth, and the best mining is that which does its work at the minimum of cost and with the maximum of profit. The gold miner uses many of the methods employed in mining for commoner materials, but he adapts them to suit his particular difficulties, and adopts many special contrivances of his own. The distribution of gold in nature is governed by its special properties, and they also determine the methods by which it can be sought and won. Thus, the reluctance of gold to enter into combination renders even the smallest grains of it almost indestructible, for they neither rust nor dissolve appreciably in any common solvent. The brilliant colour, which gives gold its decorative value, causes minute specks of it to be readily visible. Its unequalled malleability enables grains to be hammered out into broad flakes, which are conspicuous out of all proportion to their bulk. The relative scarcity of gold, which makes it a suitable standard of value, leads men to mine it in the remotest and most inaccessible corners of the globe, and enables them sometimes to earn a profit by extracting it from deposits, which contain only one part of gold in over 200 million parts by volume of earth. This remarkable feat is possible only owing to the exceptional heaviness of gold, which causes its natural concentration on river beds and allows its easy collection in miners' sluices.

THE SOURCE OF GOLD.

All the gold that is accessible to us must have come from one of two sources—the sea or the igneous rocks of the earth's crust. Sea water contains a small trace of gold; and if the vast volume of sea water has in solution even a very minute proportion of the metal, the oceans must hold a quantity which, if it could all be extracted, would render gold a drug upon the market. The prospects of extracting gold from sea water as a commercial process are not hopeful. Liversidge estimates the amount at about a grain of gold to the ton of sea water, but, according to Don, the sea contains only ·07 grain per ton, or about 1-100th of the amount which the waste waters of many cyanide plants are allowed to carry away in solution.

So far from the sea being the primary source of gold, there is no well-established case in which the gold found in the rocks has been deposited in them by precipitation from the sea. Whatever gold there may be in sea water has probably been obtained by the solution of gold grains upon the shore, and it is, therefore, secondary and not primary in origin.

Hence we are driven to seek the original source of gold in the only alternative—the interior of the earth. The one fact certainly known about the interior of our earth is that it is much heavier than the rocks which compose its outer crust or shell. This view was advanced as an hypothesis by Isaac Newton, and it was demonstrated in 1774, when Maskelyne, using Mount Schiehallion, in Perthshire, as his weight, and a plumb line as his balance, actually weighed the whole earth. He found that its density is nearly twice as great as that of the rocks which form its crust; and later measurements have proved that the internal mass of the earth is even heavier than Maskelyne thought. The central mass of the earth is so heavy that Posepny appropriately named it the "barysphere," or heavy sphere. The

simplest explanation of the great weight of the barysphere is that it is loaded with heavy metals; and, according to the calculations by Hutton, in 1779, based on Maskelyne's observations, the heavy "metalline part," as Hutton called it, must occupy $\frac{20}{31}$, or nearly two-thirds of the diameter of the earth. Direct evidence in support of the concentration of metals in the interior is supplied by the fact that the primary ores of gold occur either in those old rocks which have once been deepest below the surface, or in localities connected with the interior by fractures in the crust or by volcanic action. Alluvial gold may be found in rocks of any age, from Archean times to deposits that are still forming. But the majority of the gold-bearing lodes of the world, as in Russia, India, South Africa, Brazil, and many of the gold-fields of North America and Australia, occur in very ancient rocks that have been at one time deeply buried beneath the surface, or were formed nearer the earth's barysphere than later deposits.

The gold found in veins in the younger rocks occurs chiefly along great fractures through the crust, as in the Sierra Nevada of California, or else in association with igneous rocks that have been forced up from below, such as the volcanic neck of Cripple Creek, in Colorado, and the intrusive igneous rocks of the Thames Goldfield, in New Zealand. In both cases the gold in the younger veins has, doubtless, been brought up from below by vapours or solutions escaping from the deep, intensely-heated barysphere.

Alluvial Gold.

Gold ores may be divided into two groups—primary ores, wherein the gold has been introduced in solution, such as veins, lodes, or masses; and secondary ores, into which the gold has been carried in fragments, derived from primary ores by the mechanical action of wind or water. (Fig. 1). Alluvial gold is derived from the destruction of primary gold-bearing deposits. The light, earthy material in the lodes is swept away by wind or stream; but gold, being nearly eight times as heavy as its usual companion, quartz (the specific gravity of gold being 19·33 and that of quartz 2·6), does not travel far. It comes to rest all the sooner owing to its softness, for the angular grains are worn into rounded pellets, and the flakes are rolled into cylinders, which from their size and shape are often called "mouse droppings;" and the gold, therefore, offers little surface to the water.

Fig. 1.

The Kum-Tow Gold Nugget, from the Rheola Goldfield in North-Western Victoria. From a photograph issued by the Mine Department, Victoria. The nugget was discovered on April 17, 1871, at the depth of 12½ feet. Gross weight, 795 oz. 19 dwt.; value £2,872.

In arid regions, or in positions where the decomposed lodes are exposed only to the action of wind and occasional rain, the gold remains in rough particles, close beside the lode from which it fell. It is known as "shed

gold," and may be recognised by the angularity and raggedness of the grains. Where, on the other hand, the gold is carried along by a stream, it is rolled into the rounded forms characteristic of water-worn gold.

Gold Washing and Sluicing.

The first stage in the history of a gold-field is generally the discovery of its alluvial gold. There is a "rush" to the locality; the miners peg out their claims, according to the regulations of the local law, and they dig shallow pits into the gravel or coarse sand, in which alluvial gold generally occurs.

The simplest method of extracting the gold is to wash the "dirt," as it is called, in a tin dish or pan. An ordinary tin dish when well heaped up holds 20 or 25 pounds of earth, and there are usually about from 150 to 180 dishfulls to the cubic yard. The material is stirred with water, the washed pebbles are picked out by hand, and by a swirling motion of the water the earth is washed away and the heavy metallic particles left in the dish. The gold is in the form of grains and thin specks known as "colors;" on the average about 35 colors weigh one grain. If the gold collected from one dishfull weighs one grain the material is worth about four dwt. to the ton, or six dwt. to the cubic yard.

The tin dish is only serviceable in prospecting, in working small pockets of very rich ore, or in extracting gold which has been concentrated by some other process, such as sweeping the surface of the bed rock exposed by the removal of the overlying gold-bearing gravels.

Poorer ores must be handled in larger quantities, in some such machine as the miner's cradle. It is a box about three or four feet long, one and a half or two feet wide and deep. The top of the box consists of a sieve into which the earth is shovelled, water is poured on to the earth from a can, and the material is washed by swinging the machine to and fro on its rockers. The fine material falls through the sieve on to a sloping piece of wood covered with plush, on the rough hairy surface of which the gold is collected, while the lighter mud and sand are swept away by the current. This machine, a Californian invention, is very efficient in the recovery of fine gold. Poorer material may be treated by being washed by a stream of water down a long trough or sluice-box, of which the modern form is popularly known as a "long tom." The long tom consists of a trough, usually about 12 feet long and 20 inches wide, with a slope of about one inch in a foot; the floor of the lower part of this trough is crossed by a series of ridges which catch the gold.

The long tom is suited to the requirements of a small party of working miners; for operations on a larger scale the same method is used, but there is a longer "sluice." It consists of a very long trough or channel, composed of a series of wooden sluice boxes, like the long tom, or of a trench cut in a rock, or of both. Thus the Colombian Hydraulic Company used a sluice composed of 2,839 feet of boxes and 502 feet of trench cut in rock. Such long sluices requires hundreds of sluice boxes, placed end to end, they are sometimes about a mile in length. The usual grade is a fall of about 1 in 24.

If the gold-bearing material is so compact that it does not readily fall to pieces in water, then it has to be crushed before it can be washed; it may be broken by being pounded in a tub of water with a dolly; or it may be broken up on a larger scale in a puddling machine, in which the power is supplied by a horse, water-power, or steam. This process of puddling may be used where water is so scarce that it cannot be allowed to run freely away as in sluicing.

In these various contrivances the essential procedure is the same. The material is stirred up with water, which washes away the light earth, while the heavy gold is caught on the floor against ridges of wood or angle iron, known as "riffles," or upon rough surfaces such as blankets, or by means of mercury, with which gold readily combines as an amalgam.

The grade of ore which can be worked by these devices depends upon the scale on which the material can be handled. The greatest achievement in mining on these lines is the system of hydraulic sluicing, which we owe to California. The gold-bearing gravels occur there on the flanks of the Sierra Nevada, so water can be impounded in reservoirs at a higher level and brought to the mine by a ditch or race. The water falls down a steel or iron pipe (coated inside with asphalte to prevent it rusting) to the level of the gold-bearing deposits, against which it is directed by a huge nozzle, usually called a "Giant." The water leaps from the nozzle and falls with such force on the cliff that it tears away the materials like a steam navvy. For example, at Fresno, in California, the pipe line from the open race to the nozzle was 4,020 feet long, and had a

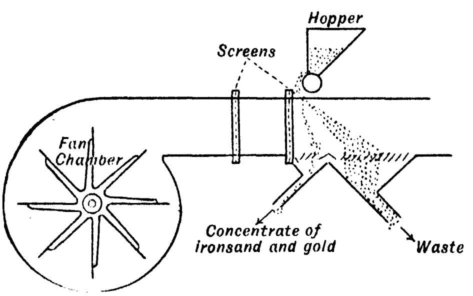
fall of 1,411 feet. The weight of the column of water was 317 tons, so the pipe increased in thickness from ¼ inch steel at the top to ⅝ inch steel at the bottom. The water was discharged through a nozzle 1½ inch in diameter, with a thrust of 93 tons, at a speed of 100 miles per hour.

Such a powerful jet digs into the base of the cliff and undermines it; the gravel falls in huge masses which are broken up by the play of water, and the loose material is swept away down the sluice. Large stones, fifteen pounds in weight, are carried along like corks, while the heavy grains of gold rest against ridges, or are caught by mercury in depressions on the floor of the sluice.

This system of mining is cheap where abundant water-power is available. The water may have to be collected in some distant valley and brought to the mine by a long and costly aqueduct. But where water and a good fall are locally available the equipment is inexpensive, the power costs practically nothing, and little labour is required. In such cases hydraulic mining has been profitably employed upon deposits, which yield only one part of in gold every sixteen million parts by weight of earth.

Modifications in the system of hydraulic sluicing are required under different geographical conditions. Thus in the famous Arctic goldfield of the Klondyke the ground, being permanently frozen, has to be thawed by fires before the gravels can be disintegrated and washed. A very different method of

FIG. 2.



THE EDISON DRY CONCENTRATOR (after Chapman).

alluvial mining is necessary in arid tropical regions. Hydraulic mining is impossible on the plains of Westralia, where water has often cost one shilling or even two shillings a gallon, and was far too expensive a luxury to use in gold washing. Hence the Westralian miners developed the system of dry blowing; gold-bearing earth is crumbled to powder and allowed to fall in a stream before a pair of bellows, which blows the light sand and clay aside, while the heavy gold falls vertically on to a tray. Edison's dry concentrator (Fig. 2) is a more elaborate machine of the same type. It is used, *e.g.*, in the Golden Mountain of New Mexico; the blast is produced by a powerful fan, and acts on the sand, falling across a tube; the sand is blown along the tube while the gold and black iron-sand fall into a separate hopper. The concentrate is then allowed to fall like solid rain before some powerful electric magnets; they attract the black iron sand and the dry separation of the gold is thus completed magnetically.

In other gold fields, sluicing is prevented by the presence of too much water. River beds are often auriferous; and the simplest method of obtaining this material is to build a wing dam, forming a dock in the river; the dock can be emptied by a Californian pump, driven by the river current, and the material on the bed then mined and treated.

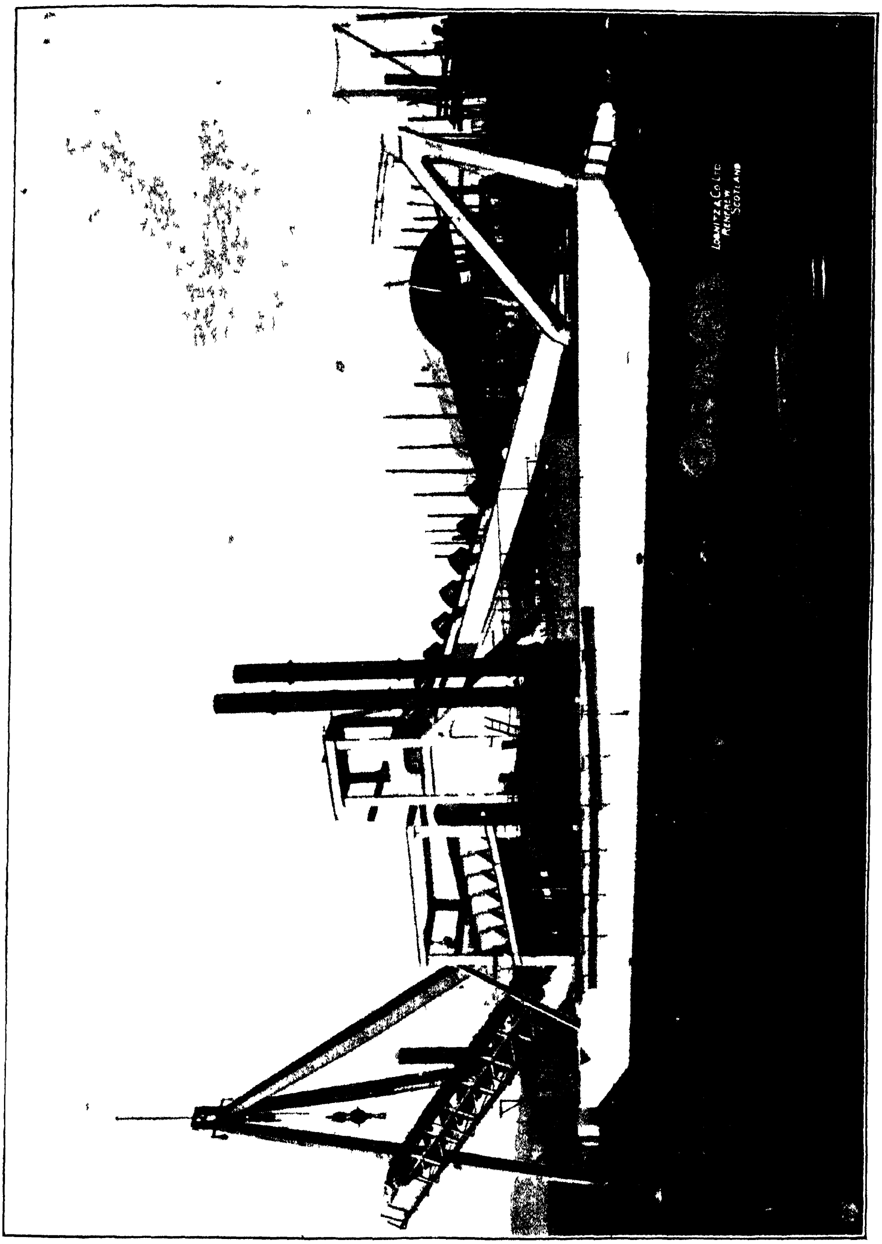
A second method is to divert the river from its course by cutting a canal or tunnel through a spur of land, and thus draining a whole reach or meander of the river. This work may be expensive; but it leaves bare a considerable area of river bed. This method is at least as old as Job, who tells us that the miner bindeth the rivers that they flow not. One of the best known modern cases was the binding of the Feather River, in California, so that it no longer flowed through the loop of its channel occupied by the Cape Claim, near Oroville; the miners recovered £120,000 of gold before the river suddenly retook possession of its bed.

GOLD DREDGING.

During the past twenty years, a new and still more effective method of working gold-bearing river beds has been developed owing to the inventive ingenuity of the miners in the Dominion of New Zealand. Many of the rivers in the South Island of New Zealand could not be conveniently diverted or worked by wing-dams; so the miners scooped up the gravels beneath these rivers in a small trawl or "spoon dredge," consisting of a leather bag, armed with a steel rim or lip. It was fastened to a pole, and dragged over the river bed. In 1881 it occurred to Mr. McQueen, of Dunedin, "the father of gold-dredging," that the bucket-dredge, well known from its use in deepening rivers and harbours, might be used to replace

this crude contrivance The "Dunedin Gold Steam-Dredging Company, Limited," was founded, a dredge built, and successfully employed, in 1882, on the Clutha River, in New Zealand Its success marks the real foundation of the great industry of gold dredging

FIG 3



A GOLD-DREDGE (from a photograph lent by Messrs Lobnitz & Co, Renfrew) The chain of buckets and its boom are seen over the right-hand half of the dredge The gold separating apparatus is raised to the left of the boilers. The tailings elevator is raised projecting from the stern of the dredge beneath the crane

The simplest, and as a rule the most economical type of dredge, consists of a barge, from which a chain of buckets on a continuous, jointed ladder is forced against the river bed by being hauled round the end of a boom, the buckets dig up the gravel, lift it above the deck and discharge it on to a sloping platform of bars—a grizzly The grizzly separates the

large boulders which slide down it on to the deck of the dredge, or fall into a boat, from which they can be dumped safely out of the way. The finer material passes between the bars of the grizzly into a cylindrical revolving screen, known from its shape, as a "trommel," the German word for a drum. The pebbles run in a stream down the inside of the screen; while the fine material falls through the holes on to the washing tables; the fine clay floats away in the water; the sand is washed down the sluice boxes, where the gold is caught against obstacles, or in the hairs of the baize, coco-nut matting, plush or blankets on the

FIG. 4.

floor of the boxes. The barren waste material or "tailings" were at first dropped over the stern of the dredge, whence it soon worked forward and was redredged. The re-working of the material was such a ruinous waste of power, that the river could only be dredged in patches; but after several attempts a successful tailings elevator was invented in New Zealand in 1894, and after that date the dredging industry made rapid progress. The usual forms of tailings elevator consists either of a chain of buckets or of a revolving belt, which raises the waste material and drops it behind the dredge in a heap on the shore. Another form is the Payne-Peck elevator, a centrifugal machine that spits out the waste material and throws it on to the bank. The advantage of this contrivance is that it obviates the need of so heavy and expensive a dredge as is required to balance a large elevator.

The use of dredges is not confined to the actual river courses for which they were at first designed; they mine alluvial flats and flood plains beside rivers with equal success. A pit is dug and flooded, and the dredge floated in it. The dredge not only hauls up the material on the floor of the pit, but tears away the sides; it gnaws its way through an alluvial plain, filling up its track behind it with the waste material.

The second type of dredge, the suction dredge, works by a centrifugal pump instead of by buckets. It is really a gravel pump, which pumps up gravel instead of water. It may be used in places where the bucket dredge will not work; thus on a hard, rocky river bottom the gold may rest in crevices, from which the bucket dredge could not collect it, unless the bed rock has been shattered by blasting, so that the rock can be raised by the buckets. A suction dredge, however, can suck the bed rock clean. Suction dredges are mainly of value for use on alluvial flats, where the bed rock is hard and irregular. In such positions the dredge rests on the ground; a hole is dug before it down to bed rock; the adjacent gravel is washed into this hole by jets of water as in hydraulic sluicing; the gravel is sucked up by the pump and discharged over the gold-saving tables or down a long tail race, When the ground has been worked from the front of the dredge the hole is filled with water; the dredge is floated into a new position and the process repeated as before.

Dredging can be applied to any gold-bearing deposits which lie in comparatively level sheets either beneath or beside a river or upon a sea beach. Much of the success of gold dredging is due to the certainty with which the ground can be sampled, and provided the prospecting work is properly done and a dredge is selected suitable to the local conditions, this type of gold-mining appears to be unusually free from financial risk. The method of prospecting must vary with the local conditions; on a wide alluvial flat from one to four drill-holes in every ten acres may be sufficient. The gravel or sand is raised by a suction-pump from the bottom of the drill hole, and the gold carefully panned from the wash.

Gold dredges are successful because of the marvellous economy with which they handle great quantities of material. Some suction dredges which I once visited at Yackandandah, in Victoria, were earning a profit from ground that had been worked over four times by whites, and abandoned as useless by Chinese. Under favourable conditions a dredge will haul a cubic yard of earth from a river bed, sort it, wash it, and extract its gold for twopence, and sometimes even for less. The Vaughan bucket dredge at Castlemaine, during 1905, worked at a cost of 1½d. per cubic yard, and paid dividends by working deposits which yielded only ·96 grain of gold per cubic yard. According to Verschoyle, there are cases in New Zealand in which the work has been done for under one penny a cubic yard, or three farthings a ton. Hence dredges may earn a handsome profit with a recovery of two grains, or fourpence worth of gold out of every cubic yard of gravel. The average yield of all the bucket dredges in Victoria in 1905, was 2·04 grains, or four pennyworth of gold per cubic yard, or three pennyworth per ton. The Victorian suction dredges in the same year recovered an average of 3·12 grains.

Deep Leads.

Gold dredging is an invention that has enriched most gold-mining countries. Another system of alluvial mining is of more limited application, but it happens to be of especial interest at the present time. It is the working of the deep leads of Australia. A deep lead, according to the Mines Act of Victoria, 1898, is, "any watercourse or gutter below the surface of the earth, containing alluvial deposits at a depth of not less than 100 feet from such surface."

The Australian mining industry began in 1851, and its first great success was the discovery of the rich alluvial gravels of Golden

Point, Ballarat, on 24th August, 1851. The gravels there were exceptionally rich: for their gold had come from very rich lodes, and it had been twice concentrated by river action. The fame of the field was increased by the discovery of its gold nuggets, or masses of almost solid gold lying in the alluvial beds. The largest known nugget, the Welcome Stranger, which contained 190 lbs. of gold, was found at Moliagul; but the second largest, the Welcome Nugget, was found at Ballarat in 1858; it weighed 184 lbs. 9 oz. 16 dwt., and was sold for £10,000. These sensational nuggets, even more than the richness of the gravel in bulk, made Ballarat the most attractive of the early Victorian goldfields.

Some of the deposits first worked at Ballarat lay on the beds of existing streams; but the richest material, including the gravel of Golden Point, was in old river beds known as "leads." The miners followed these leads, till their work was stopped against a cliff of the igneous rock, which formed the plateau of Ballarat West. It was feared that this igneous rock had completely destroyed the lower courses of the old rivers. This rock wall repelled the army of miners who were camped on the plain beneath as successfully as the walls of Sebastopol were then resisting the allied armies in the Crimea. Hence the plateau received its name of Sebastopol.

It was predicted by a Mr. Thomson, one of the staff of the Port Philip Mining Company, that the leads would be found to continue under the plateau of igneous rock; but the miners would not believe it, and insisted that the leads must pass southward along the face of the plateau down the present valley of the Yarrowee Creek. No traces, however, of the old river, in this direction could be found.

At length, in August, 1854, some miners at the White Flat Rush, at Creswick, a goldfield ten miles north of Ballarat, who were faced by the same difficulty, drove a tunnel straight at the face of the basalt. They discovered that instead of the rock being a thick, deep-seated mass like a granite, it was only a thin, superficial sheet like a lava, and beneath this rock the gravels were continued and safely preserved. This enterprise began the system of deep lead mining.

When the news reached Ballarat, the miners renewed the attack on their Sebastopol; they mined beneath its wall, traced the Frenchman's Lead beyond it, and thus began the mining of the buried gravels of Ballarat West. As they worked away from the edge of the plateau, they found it more convenient to reach their work by digging a shaft down through the basalt to avoid the great length of tunnel that would otherwise be necessary. The first shaft was put down in October, 1855. In the following year (June, 1856), the miners tried to economise work, by prospecting ahead of the actual mining. For this purpose they began the first of the innumerable boreholes which have been put down to discover the course of the buried leads.

Deep lead mining was comparatively easy where first developed at Creswick and Ballarat, for the general course of the lead was followed inward from its outcrop, and the water in the deposits could be removed without undue difficulty. The success of deep alluvial mining at Ballarat led men to consider the possibility of discovering leads beneath the other basalt plains of Victoria.

Large tracts of the State of Victoria are occupied by plains, and deeply buried beneath them is an old land surface with its valleys, river channels, and hills. In northern Victoria the plains are formed chiefly by the thick wide-spread silts of the Murray basin; in southern Victoria the most important plains are due to sheets of basalt which have flowed from numerous volcanic vents. At Ballarat the basalt has smothered the old divide between the rivers that formerly flowed directly southward into the Southern Ocean, and those that were tributaries to the Murray. The basalt plateau of Ballarat projects in long narrow bands, which extend for 50 miles to the north. These lava bands stand up above the general level of the country as plateaus, while the existing rivers flow through young valleys cut into the soft rocks on the edges of the lava.

The idea occurred to some members of the staff of the Geological Survey of Victoria that these lava plateaus represented ancient river valleys, that had been filled by basalt. After the close of the volcanic eruptions, the rivers were forced to cut new channels along the edges of the lava flows; hence in time the banks of the old valleys were worn down, while the floors of the valleys have been left upraised owing to the resistance of the hard basalts that filled them. This theory offered the only reasonable explanation of the distribution of these lava bands; and, if it were true, the old river beds, with their gold-bearing gravels, must still lie buried beneath the lava flows. The discovery at White Flat Rush in 1854 proved that the rich shallow leads of the Creswick

Goldfield passed beneath the edge of the basalt sheet that flooded the old valley of the Loddon.

Krause's map of the Creswick Goldfield, published by the Geological Survey of Victoria in 1870, showed that the former course of the Loddon could be fixed between fairly narrow limits. The site of the old river banks is marked by the outcrop of the slates and sandstones on either side. The first practical suggestion for the search for the old leads was made in a report by Mr. R. Murray, then the acting Government geologist for Victoria. He reported (30th September, 1878) that from the geological survey of the country to the north of Creswick,

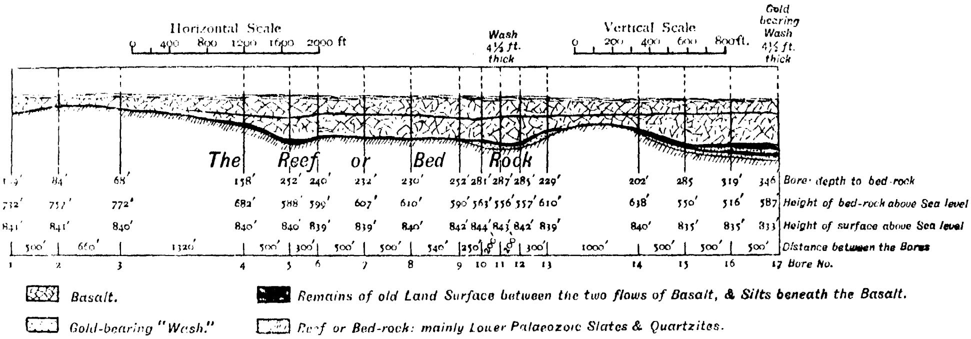
"It appears beyond a doubt that two main deep lead systems, fed by tributaries, pass eastward of Clunes, and unite to the north-east, between Eglinton Swamp and Glengower. The eastern of these two systems embraces the rich leads now being worked northward from Creswick and Kingston, probably fed by others, among which may be the extension of the Rocky lead. Of the western system little or nothing is known Its existence is indicated by the basalt covering the country between the schistose rocks exposed at Clunes and those which form the western wall of the Creswick leads."*

Murray pointed out in his map the outlet through which the old river must have passed, and he proposed to put down a bore half way across this gap to discover approximately the probable depth and position of the lead.

This prediction has been amply justified by the results. The leads have been discovered and mined both in their upper reaches near the margin of the lava sheet, and lower down their course far out into the basalt plains.

In mining part of a deep lead it is first necessary to determine its exact position and depth. There is no indication on the surface of the site of the old river channel; the ground may be a bare level plain which is quite independent of the undulations of the former land. A line of bores is put down through the basalts and underlying drifts to the bed rock, and from the bore records a section is drawn showing the contours of the buried land surface. (Fig. 5). This section shows the position of the river channel or "gutter," as well as its depth and width and the thickness of its gravels. The material brought up from the bores also shows whether the drifts contain gold, but the samples collected from the bores are so disturbed that they may not give reliable evidence as to the gold-value of the drifts.

FIG. 5.



SECTION SHOWING RESULTS OF 17 BORES in the Parish of Moolort, on the basalt plateau of the Loddon Valley, made to discover the buried leads. (Reduced from the Section by Stanley Hunter: 1898.)

The bores also give useful evidence as to the nature of the rocks beneath the lead. For coarse gold usually travels so short a distance that a lead is not likely to be rich at a point far from a source of gold. Where the old river crossed and recrossed a belt of gold-bearing lodes its gravels may be expected to be rich; but if it be crossing rocks that contain no gold, then the lead will doubtless be poor.

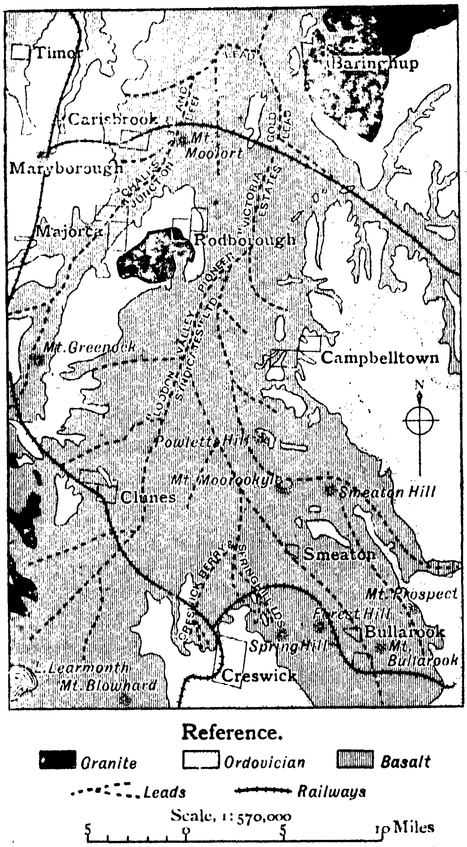
By numerous lines of costly borings, most of which have been made by the Government of Victoria, the distribution of many of the deep leads of that State has been determined. The old valleys have been discovered buried beneath the silts of the Murray at Chiltern and Rutherglen, and under the basalts of the Loddon valley, the Ballarat plateau, and other districts of Victoria. The Loddon leads are the longest and the greatest; and as the rivers there crossed a belt containing many gold-bearing lodes, their gravels are often rich in gold. The position of the leads has been determined in so many places, that the general

* Progress Report Geol. Surv. Vict., No. VI., 1880, p. 48.

course of the old Loddon River and its chief tributaries has been discovered; and it can be represented on a map like an ordinary superficial river (Fig. 6); but it must be remembered that this river is sometimes buried under 500 feet of lava.

The course of the leads having been determined, the engineer proceeds to drain them.

FIG. 6.



SKETCH MAP OF THE DEEP LEADS BENEATH THE BASALT PLATEAUS OF THE LODDON VALLEY, VICTORIA. (After Stanley Hunter.)

This is often a long and costly business; for the beds are water-logged, and their own water has to be removed; and while this water is being pumped out of the lead more flows in. It may come from two sources—rain water which runs in from the sides, and deep-seated plutonic water, which is recognisable by its higher temperature. The pumping plant has, therefore, to lift all this incoming water before it begins its main work of reducing the old accumulations in the drifts.

Mines have pumped a million gallons a day for seven years before being able to mine any of their gold-bearing material. The Great Southern Company at Rutherglen pumped two million gallons a day for five years. During recent years the necessity of having such powerful pumps that the accumulation of water can be rapidly dealt with, has been recognised; for if a lead can be drained in one year instead of seven, the pumping of the six years inflow is saved; and if the pumps can only keep pace with the incoming water the mine might go on pumping for ever. Quick pumping is, therefore, economical; and acting on this principle the Loddon Valley Goldfields has erected a pumping plant capable of lifting 6,000,000 gallons of water a day; and that mine and its neighbour, the Victorian Deep Leads, pumped in January, 1906, no less than 250,000,000 gallons of water in one month.

When once the gravels have been drained they are so easily and cheaply worked, that they often give returns which well repay the cost of pumping. The Madame Berry Mine, at the head of the Berry Lead, on a called-up capital of £15,000, raised no less than £1,588,515 of gold; and paid over £900,000 in dividends and royalty.

There are two chief methods of deep-lead mining; the method selected depends largely on the hardness of the rocks that have buried the lead.

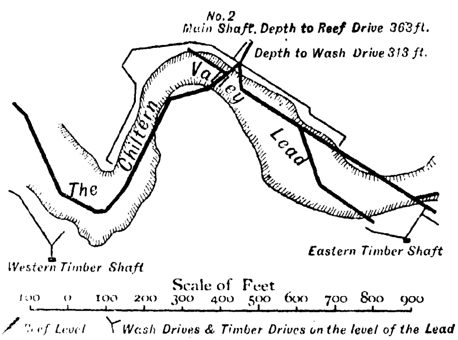
In both systems the first operation is to put down a shaft. A site is chosen where, if possible, the solid bed-rock is exposed at the surface or it is known that the shaft will go at once from basalt into bed-rock without the risk of passing through quicksands. Where, however, shafts have the one misfortune to encounter soft water-logged beds, the difficulties may be overcome by making the loose ground solid by freezing it until the shaft has been made and lined.

The main shaft is carried down into the bed-rock to a depth well below the deepest point on the lead. A drive is then made from a point a little above the bottom of the shaft through the bed-rock, or "reef"; this drive is therefore known as the "reef drive." It is carried under the lead, and bores—3-inch pipes—are then pushed up from it into the gold-bearing beds; their water rushes through the bore-holes into the drive, and flows along it to the pump chamber at the foot of the shaft. The number of bores opened is determined by the capacity of the pumps. As soon as the ground is sufficiently drained a rise is put up from the reef drive into

the lead. The gravel, known as the "wash," is then dug out, and dropped down shoots into the reef drive, where it is run to the main shaft and hauled to the surface.

In the second plan of working a deep lead mine, drives are made from the shaft at two levels; the lower one—the "reef drive"—is the main permanent drive of the mine, and is used for hauling and ventilation. (Fig. 7). The upper drive runs up at once into the wash, and is known as the "wash drive"; it helps to drain the lead in its neighbourhood, and from it cross drives are made to the edge of the lead; from the end of each cross-drive, a lateral drive is pushed forward along the edge of the lead. The ground is therefore blocked out by three longitudinal drives in the wash; the

FIG. 7.



PLAN OF PART OF THE CHILTERN VALLEY GOLD MINE, in the Chiltern Goldfield, Victoria. (Reduced from a Survey by Stanley Hunter.)

wash is dug out and dropped into trucks on the reef drive, which follows behind the work in the wash, thus avoiding the waste of unnecessary branches of the expensive reef drive.

In calculating working costs in these lead-mines, the unit is not the ton but the square fathom; for most of the gold is in the bottom of the wash, and as much gold may be got from wash three feet thick as from wash six feet thick.

The extraction of the gold is done by simple puddling. The process consists of washing the material, sorting out the cleaned boulders and stones, and then collecting the gold from the fine sediment by the use of blankets, riffles, or mercury. As the mines are situated on level plains where there is no natural fall, the puddling machinery is erected on platforms high above the mouth of the shaft. The material then falls through the gold-separating apparatus by its own weight, and the waste can be run on to dumps across a raised tramway. A deep lead mine can be recognised from a distance by its high poppet legs, and by the huge piles of washed quartz boulders and pebbles extracted from the wash.

SCOPE OF ALLUVIAL MINING AND CHOICE OF METHOD.

Some years ago the idea was prevalent that alluvial mining had done its work, and that it would soon be numbered among the extinct industries; for although new finds, such as those which have been made at Klondyke, in Siberia and South America might start fresh local centres, the room for such discoveries was being rapidly narrowed. But the combined work of the engineer and the geologist has given fresh impulse to alluvial mining. The field of its operations is steadily growing with the increasing capacity of modern mining methods. The three main systems of alluvial mining are each suitable to special areas. Deep lead mining is the most restricted geographically, and is at present confined to Australia; but it will no doubt be found applicable in some African localities.

Hydraulic mining requires an abundant water supply, a good fall, and thick gold-bearing deposits. So it is suited to mountainous country with an ample rainfall, where gold-bearing beds occur on the sides of deep valleys; and it can be most economically applied to deposits from 150 to 200 feet in thickness. If the beds are thinner, then much time is lost in continually extending the pipes and the sluices to reach the fresh ground. If the beds are thicker the face falls away in dangerous and unmanageable masses, and the mine may have to be worked in two benches.

Dredging offers the widest possibilities, for it may be applied to any level sheets of gold-bearing alluvium. It may be used on any sea beaches, river beds and riverine plains where the alluvium is not too deep for the tailings elevator to lift the refuse on to the bank. The use of dredges has also spread from Australasia to North America, Siberia, Servia, Burmah and West Africa, and they have been tried in South Africa. We need not accept the confident prediction that the dredges will make so great a contribution to the gold yield of the world that they will have a revolutionary political influence, raising the prices of all other commodities by lowering the price of gold. But the supply of low grade material which the dredges can work is so vast and so widespread that they promise to extend in-

definitely the life of alluvial mining: all the gold-producing countries of the world are, or probably will be, indebted to the ingenuity of the New Zealand miners who have shown us how to collect gold from these low grade deposits, in which it would otherwise have lain beyond our reach.

THE CRICKET-BAT WILLOW.*

By W. J. Bean.

No question in connection with profitable tree-planting has aroused greater interest in recent years than that as to the kind of willow best adapted for the manufacture of cricket bats. It has only attained importance in recent times, because it is only lately that the supplies of the best "bat willow" have become seriously limited, and that prices have risen in proportion. At a sale of willow trees on Sir Walter Gilbey's estate at Sawbridgeworth, in February, 1906, the best "bat willow" realised prices estimated to be equivalent to about seven shillings per cubic foot. I have recently been informed by the agent of a large estate in Essex that he had declined the offer of £1,500 for the best 100 willows on the estate; and Mr. John Shaw, of the well-known firm of Shaw and Shrewsbury, of Nottingham, last winter offered £40 for a single tree. When it is remembered that trees have been known in favourable situation to reach a saleable size in twelve years (having in that period attained a girth of about 50 inches) these prices show that there is no timber so profitable at the present time as that of the cricket-bat willow. It is not surprising, therefore, that the attention of owners of land suitable for the growth of willows should have been attracted by this tree. As a matter of fact, a large number of willows have been planted during the last few years with a view to meeting the future demand; but we have it on the authority of Mr. Shaw, one of the largest buyers, as well as a leading expert, that not more than one-fourth of the trees that are being planted are the best cricket-bat willow.

The identity of the true "bat willow" has always been obscure. The cricket-bat maker recognises the tree best suited to his purpose with infallible certainty, but the characters on which he relies are not characters on which the botanist bases his distinctions. It is with a view to helping the planter to recognise the willow best suited for cricket bats, and to avoid the unsuitable ones, that the matter is now being taken up in the *Kew Bulletin*.

It has for some time been evident to us at Kew that there is more than one willow valuable for bat making, although, perhaps, not equally valuable

* Reprinted from the *Kew Bulletin*, No. 8, 1907. The original articles contain two plates, one of the best "close-bark" willow (*Salix alba*, var. *caerulea*) and one of the "open-bark" willow (*Salix fragilis*).

It has also been evident that whatever the best "bat willow" might be, it is not so much a species in its entirety as a variety or, perhaps, merely a local form. With a view to settling the identity of the true kind the Copped Hall Estate, near Epping, the property of Mr. Wythes, was visited in company with Mr. Shaw. Here a large quantity of "bat willows" are growing, and specimens were collected of the different sorts whose respective values for bat-making were certified by Mr. Shaw. They have since been botanically identified, and for assistance in this work we have to express our obligations to the Rev. E. F. Linton, M.A., the well-known authority on British willows. The expert knowledge of the cricket-bat manufacturer has, therefore, been joined to that of the botanist, and it now remains to put on record the conclusions at which we have arrived.

The "Open-Bark" Willow (*Salix fragilis*, L.).

The two commonest terms used in describing willows from the bat-maker's standpoint are "open-bark" and "close-bark." There is no difficulty or mystery about the "open-bark." It is the crack willow—the *Salix fragilis* of Linnæus—a common tree on the banks of the Thames near Kew. Although a useful timber in other respects, it is of very inferior merit for the making of cricket bats. It is, in fact, used only for the manufacture of cheap bats for children, such as are sold in toy shops, rather than by the genuine athletic outfitter. They are of a reddish colour. In connection with the present question, the "open-bark" or crack willow should only be known in order to be avoided.

Botanical characters of *Salix fragilis*.—A tree 80 to 90 feet high, with spreading branches; branches growing at angles of 60° to 90°. Leaves coarsely serrate, usually somewhat pubescent at first; pubescence deciduous. Stamens silky at extreme base only. Ovaries, in the commonest (probably unfertilised) state, almost subulate, but ovate-lanceolate in the fertilised condition, gradually narrowing to a distinct style; their pedicels ultimately three to four times the length of the nectary.

The Best "Close-Bark" Willow.

(*Salix alba*, L. *caerulea*, Syme [*S. caerulea*, Smith]).

The willow selected by Mr. Shaw as the very best one for bat-making is a tree of markedly pyramidal habit; it is female or seed-bearing, and it belongs to the bluish-leaved variety of the white willow. It is, therefore, a pyramidal form of *Salix alba*, var. *caerulea*. The bark is less rough than in *S. fragilis*, and the corrugations are less prominent, straighter, and more continuous up and down the trunk of the tree. The wood is white, and when it is being split does not part so easily as the "open-bark" does, but splinters a good deal. This splintering or tearing down the cleft is regarded as an evidence of good quality.

According to Mr. Shaw this particular tree is only

to be found at the present time in the counties of Essex, Hertford, and Suffolk. A few trees were at one time growing in Kent and Surrey, but it is his belief that the true "bat willow" is no longer to be obtained there. Neither Cambridgeshire nor Lincolnshire has it, nor does it exist (except for recent plantings) north of the Trent. This all goes to show that this willow is a local form, and that only those "sets" can be relied on which have been obtained from the right district. *Salix alba*, var. *caerulea*, is grown at Kew, where there are two fine specimens on banks of the lake. But although in character of leaf and fruit they are identical with the trees on the Copped Hall Estate, in habit they are quite different. The trunks have forked low, and the habit is more spreading. Although some of the Copped Hall trees are growing in hedgerows and have ample room for lateral development, their tapering pyramidal form is a most noticeable characteristic.

The pyramidal shape of the tree is associated with, and may in some measure be due to, a great vigour of growth. And it is reasonable to conclude that it this vigorous growth which gives to the timber those peculiar qualities which render it better adapted for cricket-bat making than any other variety of white willow. It is a remarkable fact that of all the hundreds of timbers now available from the tropical and temperate parts of the globe, the only tree yet known to produce a timber of the right quality is found in a few counties in England.

In regard to quality of timber for cricket bats, the typical *S. alba* appears to be intermediate between *S. alba*, var. *caerulea*, and *S. viridis* (v. below). A tree at Copped Hall was considered by Mr. Shaw to be of second rate, though of fairly good quality.

Botanical characters of *Salix alba*.—A tree 70 to 80 feet high, with ascending or erect branches growing at angles of from 30° to 45°. Leaves finely serrate, silky pubescent; pubescence permanent. Stamens more silky in the lower half than those of *S. fragilis*. Ovaries ovate-conic, abruptly obtuse, sessile or with the pedicels shorter than the nectary; style very short or absent.

S. alba, var. *caerulea*, differs from ordinary *S. alba* in the leaf being glabrescent and of a bluish green tint. The ovaries are identical.

Botanically there is no well-marked dividing line between *S. alba* and *S. alba*, var. *caerulea*, the two being united by intermediate forms. It is possible that the quality of timber improves as the tree approaches the latter.

Salix viridis, Fries.

There is another willow recognised by Mr. Shaw as a "close-bark," and of a useful quality, but still inferior to that of *Salix alba*, var. *caerulea*. Although it is not easy to put on paper the differences between the "open" bark of *S. fragilis* and the "close" bark of the true "bat willow" in such a way that they can be indubitably recognised, they are appreciated easily enough when seen in the field. But the differences between the "close" barks, although perfectly evident to the expert eye of Mr. Shaw, are by no means obvious to the uninitiated. Nor was it possible, after careful "coaching" to fix on any distinctive features in the bark as a help for future occasions. This, however, is only one more of those instances, common to pretty nearly every walk in life, where distinctions clear enough to the trained eye are quite hidden from the outsider.

But although the bark afforded no help in the differentiation of the two "close-barks," the trees were distinct enough in other respects. The habit of this second tree was more spreading than that of *S. alba*, var. *caerulea*; the leaf was smaller and not so blue; and the trees, being devoid of fruit, were presumably male. Mr. Linton considers this tree to be *Salix viridis* of Fries.

Salix viridis is a hybrid between *S. alba* and *S. fragilis*, and as these species frequently grow together, they have no doubt cross-bred very many times. It is quite probable also that the progeny have interbred with the parent species again. At any rate *Salix viridis* is a very variable tree, showing numerous intermediate gradations between the two parents—sometimes approaching *S. alba* and *S. alba*, var. *caerulea* so closely in leaf as to be indistinguishable from them, and sometimes showing very distinctly the influence of *S. fragilis*. Its advent into the cricket-bat willow question has created a good deal of confusion. A specimen approaching *S. alba*, var. *caerulea* may be described as good by the bat-making expert, whereas another approaching *S. fragilis* will be accounted inferior. Yet to the botanist both are *S. viridis*.

From the bat-maker's point of view the timber of *Salix viridis* is not so good as that of *S. alba*, var. *caerulea* because the wood is coarser and heavier. A bat made of good *S. viridis* timber would weigh about 2 lb. 7 oz. to the 2 lb. 4 oz. of *S. alba*, var. *caerulea*. The difference in market value is also so considerable as to be important to intending planters. Mr. Shaw stated that, for trees of equal size, buyers would give £10 for the *S. alba*, var. *caerulea*, but only £6 for the *S. viridis*.

With regard to the botanical characters of *Salix viridis*, it is difficult to give a concise description. It has already been explained that it is a hybrid between *S. alba* and *S. fragilis*, with which it has bred and interbred till it now forms an almost complete series of links between those two species. Therefore *S. viridis* in its various characters is more or less intermediate between the other two; this refers more especially to the angles at which the branches grow; the serration and pubescence of the leaf; the density of the flowers on the male catkins; the size of the ovaries, the length of their pedicels, and the distinctness of their styles. In some states, again, *S. viridis* has one set of organs, say leaves and twigs, resembling one parent, whilst the ovaries are almost identical with those of the other. In practice, as the late Dr. Buchanan White observed,

it requires the trained eye of the salicologist to detect and balance up the various characters that go to make *Salix viridis.*

SALIX RUSSELLIANA, Smith.

In connection with the "bat willow" question the name of *Salix Russelliana* frequently crops up, and is a source of considerable confusion. A correspondent of Kew complains that whilst one person tells him that *Salix Russelliana* is an excellent willow for bat-making, another says that it is quite worthless. The probable explanation of this is that "Russelliana" is a name that has been given to two different willows. Most commonly it has been applied to the "crack willow" (*S. fragilis*); in that connection, therefore, it indicates the very inferior willow for bat-making. But the name has also been given to the hybrid between *Salix alba* and *S. fragilis* which, as has already been explained, is itself a variable plant, but is often of good, although not the best, quality. The name "Russelliana" is now no longer used by the leading authorities on British willows, so that those interested in the cricket-bat willows would do well to discontinue its use.

POPULAR AND LOCAL NAMES.

Another source of confusion arises from the use of local names. So misleading are they, that they should be dispensed with altogether in connection with the present question, since it is hopeless now to find one popular name restricted to one particular willow. A name given to a particular species or variety may be in general use in one district, but it may be given to quite a different tree in another. In the course of consulting various works in connection with the cricket-bat willows the curious fact has been noticed that the terms "Huntingdon Willow" and "Leicestershire Willow" have both been applied to *Salix alba*, to *Salix alba*, var. *caerulea*, and to *Salix fragilis*.

PROPAGATION AND CULTIVATION.

It will have been gathered from what has been said that there is at the present time a brisk demand for young trees or "sets" of the true "bat willow." Enquiries are being continually addressed to Kew as to where they can be obtained, but we know of no one at the present time who is able and willing to supply them in quantity. It is of little use applying to the ordinary trade firms. With the best will and the most honest intentions they may supply the wrong tree, because, as has already been pointed out, it is not *Salix alba*, var. *caerulea*, merely that is wanted.

So far as our present knowledge takes us it is the erect-growing form alone that can be relied on, and then possibly the female plant only, and it is only safe to plant stock which has come originally from the counties of Essex, Suffolk, or Herts.

The usual method of propagating this willow is by means of "sets." These "sets" are branches cut as thick as or thicker than a broom-handle, with the minor branches and twigs removed; they are thus transformed into bare rods which when planted are 8 to 10 feet or even more in length. "Sets" o about this length are preferred so that the young growths may be out of reach of cattle, &c., and the young trees away from the various dangers that beset them when they are near the ground. They are also suitable for thrusting in hedgerows and such-like situations. Care should be taken to prevent cattle from injuring the stems. In some places willows are being pollarded for the especial purpose of producing "sets" of the desired size. But with the present demand for this willow this seems a slow and cumbersome means of propagation; slow, that is, to produce a large quantity; no doubt for the individual tree it may be the quickest. This willow is one of the most easily propagated of all trees, for every twig will grow. I would recommend the use of cuttings which can be made of any shoots as thick as a goose-quill and, say, one foot long. Cuttings of this character, planted in the Arboretum nursery at Kew last spring, are already (in August) six feet high. For thicker wood, the cuttings may be proportionately longer. These can be put in the ground in autumn or early spring. As they grow it would be necessary to keep them each to a single leader and to prune back the side branches and remove the lower ones as the plants grow in height. In well-kept nursery ground fine healthy plants could be produced in two or three seasons, and they could be grown to planting-out size at the rate of 8,000 or more to the acre.

Whilst these willows like abundant moisture, a position by the side of water is not necessary. The fine specimen here illustrated is, with several others, growing in a deep, rather heavy clay, with only an ordinary hedge-row ditch on one side. Mr. Shaw told me he preferred timber grown in such a position to that of trees growing close to the edge of ponds, &c.

Young trees should be watched to see that they are kept to a single leading shoot. This will obviate the forking of the trunk low down, which, of course, detracts from the value of the tree by reducing the amount of good timber. Trees, however, are more liable to fork when growing in isolated positions than they are when close together in plantations.

LONDON COUNTY COUNCIL EVENING SCHOOLS.

The London County Council desires to call attention to the facilities offered for evening instruction in the various institutions maintained by it or under its control.

In the various polytechnics, technical institutes, and schools of art situated in the county, classes in science, art and technology, music, artistic handicrafts, &c., will be re-opened towards the end of the present month. These institutions provide instruction of an advanced or technical character. Every facility is offered to different types of students to supplement workshop, office, or studio practice by evening study

under the most favourable conditions. Courses are arranged, where necessary, to prepare professional students for various examinations, art students for the examination of the Board of Education, and artisans for the examinations of the City and Guilds of London Institute, &c. The Council offers annually scholarships and exhibitions to the total value of £1,500 for competion among students of polytechnics, technical institutes, and art schools. The great success which has in the past attended the classes held at the Council's institutes and schools of art has made it necessary in several cases to provide for additional meetings of such classes to accommodate the increased number of students, and it is also proposed, provided the necessary number of students be forthcoming, to open certain new classes for which frequent application has been made.

The fees vary from 4s. 6d. to 10s. a session. In many subjects, apprentices, learners, and improvers are admitted free.

In 36 London County Council schools, centres for instruction in commercial and science and art subjects will be opened. These centres are in a degree contributory to the polytechnics and technical institutes mentioned above, and are primarily intended for students not sufficiently advanced for the polytechnic classes. Advanced work, however, is taken in many of the subjects. The instruction given in these centres includes commercial subjects, such as accountancy, banking and currency, commercial law, book-keeping, commercial correspondence, shorthand, typewriting and modern languages; science subjects, such as physiology, geology, mathematics, chemistry, hygiene, building and machine contruction; and art subjects, such as drawing in light and shade, model, freehand and geometrical drawing, memory drawing of plant form and common objects. The fees vary from 1s. 6d. to 5s. the session for one or more subjects, according to the age of the student and the character of the subjects taken.

In 237 London County Council school buildings situated in every part of London, ordinary evening schools will be opened this session. The instruction will, as a rule, be of a character preparatory to that given in the Centres, and will embrace commercial subjects such as book-keeping, shorthand, and modern languages, and general subjects such as arithmetic, geography, history and composition. Women and girls will be able to receive lessons in practical cookery, dressmaking, millinery, needlework and laundry-work; and instruction in woodwork will be provided for men and boys. Gymnastics will be taught, and lectures by doctors and nurses on first aid, home nursing, health and infant care will be given.

There are eleven special schools which provide suitable instruction for the deaf.

In 58 schools, situated in poor districts, no fees will be charged to any students, but as a rule a charge of one shilling for the session for one or more subjects will be made in the remainder of the schools.

A special effort is being made by the Council to encourage the study of English literature. Special lecturers have been engaged to deliver courses on the literature of various periods in 24 commercial centres and six secondary schools, &c. In the latter the lectures will be of a more advanced type.

The polytechnics and technical institutes will be open, as a rule, during the week commencing 23rd September, 1907. All the centres and the ordinary evening schools will be open for the enrolment of students in the week commencing Monday, 16th September, 1907.

Any persons who desire further information concerning these institutions should apply to the schoolkeeper of any of the Council's schools for a handbill giving particulars of the various institutions in the district. Full details are given in the prospectus of each institution, a copy of which may be obtained free on application at the institution.

THE PRODUCTION OF COCOA IN ECUADOR.

The principal product of Ecuador is cocoa, of which it furnishes nearly one-fifth of the world's production, now estimated at 300,000,000 pounds. The cacao tree grows on the warm lowlands and in the valleys tributary to the coast. The valleys adjacent to Guayaquil produce the greatest quantity of any district in the world. In 1900 there were 4,827 cacao plantations or farms in Ecuador, with a total of 58 million trees. The yearly production in pounds was as follows:—In 1900, 41 millions; in 1901, 53 millions; 1902, 54 millions; 1903, 49 millions; 1904, 61 millions; 1905, 47 millions; and in 1906, 53 millions. Guayaquil cocoa has a speciality of its own, both in appearance and aroma, and is easily distinguishable from the cocoa of other districts. The lower grades are very strong and coarse in flavour, while the better grades contain a larger percentage of theobroma, making them more valuable. This cocoa is divided into two classes, viz., up-river (*arriba*) and down-river (*abajo*); to the latter class belong the grades known as Machala, Balao, Naranjal, and Tenguel. The cocoa coming from the plantations situated in the up-river district is far superior and always sells at a higher price. The total annual exports of Ecuador, amount in value to £1,600,000, two-thirds of which is cacao, an article for which a world-wide demand exists, and in the production of which Ecuador enjoys a high reputation. The planting and cultivating of the cacao-tree is being carried on more extensively every year, and it is the general opinion that the article has a splendid future, and that the present production is not sufficient to meet the growing demand or consumption. The plantations are mostly in the hands of the natives, many of whom have amassed sufficient fortunes to make Paris their future home, according to the American Consul at Guayaquil. On some of the large plantations very fine residences are

found, although the owners, as a rule, seldom occupy them, preferring to live in the city. Some are also equipped with narrow-gauge railways. The United States is the largest buyer of cocoa from Ecuador, having bought in 1903 nearly nine million pounds, valued at £242,000; and in 1906, over ten million pounds, worth £292,000. In Europe, Germany gets the largest share. By statistics, France would appear to be the largest buyer, as a very large amount is sent to Havre for re-shipment, and the Ecuadorian Customs authorities enter this as consigned for consumption in France, whereas a great part of it is really not used in that country. It is estimated that the average yield of a cacao-tree is about one pound of cocoa per year, giving a planter, having a plantation of 50,000 trees, approximately 50,000 pounds of cocoa annually. When the cocoa-tree is in blossom, and the pods are commencing to grow, the appearance is beautiful. The flowers, which grow in tufts or clusters, are very small, having five yellow petals on a rose-coloured calyx. The seeds contained in each pod vary in number from twenty to forty, and are embedded in a soft, pinky-white acid pulp. The fruit is five-celled, without valves, from seven to ten inches in length, and three to four inches in breadth, of an elliptic oval-pointed shape. The rind of the fruit is very thick, and similar to a very hard, tough apple in substance, and has a slightly sweet taste.

TRAVELLING FARM SCHOOLS IN SPAIN.

The general progressive movement in Spain—a movement which is slow but sure—is expressed by a recent Government order creating a sort of travelling school for teaching scientific farming in the remote agricultural districts of the country—a measure which may have a certain commercial significance, since it will probably develop a demand for better agricultural implements and machines than those now in use. The Government order referred to provides for a course of experimental and practical instruction to be given every year by itinerant lecturers, selected from among the agricultural engineers at the district schools of agriculture. In the months of January and February of each year, the directors of these schools are required to report to the Department of Agriculture at Madrid, giving the programme of the lectures intended to be given during the ensuing twelve months, with an estimate of the cost, including travelling expenses and remuneration of the teachers, and transport of the agricultural machinery and appliances which it may be considered advisable to carry to those remote villages where the practical instruction is to be given. So far only the Schools of Agriculture at Zaragoza, Jaen, Palencia, Badajoz, and Barcelona, and the two stations at Haro and Villafranca del Panadés are referred to in this order; but if the movement proves a success it will no doubt be extended, and must lead to a wider use of modern farming appliances in Spain.

HOME INDUSTRIES.

Tin Supplies.—Although the price of tin has fallen heavily since May last, when it touched the highest price upon record, namely, £215 per ton, it is still—at £166 or thereabouts—higher than in any year since 1888, when at one time it touched £170, although during the same year it was quoted as low as £75. In 1896 it fell to £56 per ton, and the average of the year was £61. Tin is liable to these great fluctuations owing to the small production of the metal—last year the output was under 100,000 tons as contrasted with 711,700 tons of copper—and the consequent greater ease with which market movements can be manipulated. Probably there will be some further fall in the present quotation, but the decline is not likely to be great. There is a continuous though not very rapid growth of consumption, and the increase in supplies hardly keeps pace with it. On the one hand, little substitution of other metals can be effected. Glass is being substituted in increasing quantities for tin for enclosing perishable provisions, especially those containing liquid, but in other directions the demand for tin continues, and it is largely used in conjunction with other metals in the production of bronze, brass, Britannic metal, pewter, printers' type, thin sheet lead, white metal for silver plating, &c.; and solder is largely composed of tin. On the other hand, there is not much likelihood of great expansion in the output of the main producing countries. Excluding Bolivia and Cornwall, which are not included in the trade statistics compiled for trade information, the supply of tin has more than doubled during the last thirty years. In 1878 the output was about 35,000 tons, in 1906 it had increased to 75,000 tons. The Bolivian production is mostly sent abroad in the form of ore, averaging approximately 60 per cent. of metal contents, and the tin received from Bolivia has increased from 4,000 tons in 1896 to 14,700 in 1906. Although the high price of tin has encouraged the revival of Cornish mining enterprise, the output of 1906-7 was only a trifle over that of 1905—4,500 tons as against 4,468 tons. A mine that has been allowed to become flooded, as was the case with many of the Cornish mines, and where old plant has to be replaced with new, cannot get to work again immediately, but given a continuation of good prices, the Cornish output should increase considerably during the next year or two. As late as 1894 it amounted to 8,300 tons. Next to Bolivia, Australia furnishes the largest increase in output. In 1898 the shipments from that country were only 2,390 tons, last year they had increased to 6,452 tons, and information as to the industry warrants the expectation of further increase. The Straits Settlements continue to supply the bulk of the output, which, however, shows very little expansion. In 1896 the output was about 50,000 tons, in 1904 it had increased to 60,680 tons, but last year it was no more than 58,443 tons, or, roughly, three-fourths of the whole world's supply. Stocks of tin have been

heavily drawn upon, the stock and visible supply falling from 32,189 tons in 1896, to 13,118 at the close of 1906.

The Manufacture of Stilton Cheese.—Surprise is often expressed at the small quantity of Stilton turned out in this country. The manufacture is almost entirely restricted to one part of England, the centre of which is Melton Mowbray, and farmers make and buyers buy only for a part of the year round about the Christmas season. What is the explanation? Why is it that it is difficult to get Stilton, and that there is no export trade in this the finest of cheese? An acknowledged authority on the subject, Mr. James Long, deals with this question in an interesting article he has contributed to the *Manchester Guardian*, of September 3rd. Mr. Long points out that the Gorgonzola of Italy, which is of a similar character, although much inferior, is placed upon hotel and other tables throughout the whole of the year, whilst the French not only produce blue-veined cheese during most of the year—although the climate in the departments in which the cheeses are made differs little from our own—but the people eat them, and consider no important meal complete unless something of the kind is placed upon the table. The explanation seems to be that the process of production in this country is very defective. A large proportion of the Stilton made is of second or third quality. The rennet used is imperfect, and the quantity supplied too small or too large. The curd is dried too much or fails in mellowness, or, worst of all, the milk is tainted and the utensils impure. The last is perhaps the greatest failing of all, for if sweet milk comes into contact with sour milk by the use of a foul utensil it is inoculated with germs which increase with great rapidity and spoil the whole. A farmer whose dairy contains a large proportion of spoiled Stiltons usually fails to obain more than 6d. per lb. and loses money, whereas a maker of the best obtains a shilling and finds the industry a profitable one. Mr. Long gives some interesting particulars. The price paid by the Stilton maker to the farmer for good milk varies from 4½d. to 5d. a gallon. More than a gallon is required to make a pound of cheese. At the British Dairy Institute on the average of five years 12½ lb. of milk was used in May, 11½ lb in June and July, 10½ lb. in August, and 10 lb. in September, a gallon weighing slightly more then 10 lbs. Thus in May the milk at 4½d. required to make a lb. of Stilton cost over 5½d. Hence with labour, plant, rennet, wear and tear, and interest on capital laid out, there is an actual loss where 6½d. only is obtained for the cheese. The possible loss in making cheese on a large scale is considerable. When milk is bought it is paid for long before the cheese returns a penny. For example, if twenty cheeses are made daily, with 15 gallons for each cheese, the maker may have to pay a weekly cheque of nearly £40, or still more, in the early months. These facts explain why the manufacture is so small. There is want of knowledge and mastery of the work necessary to do away with the fear of loss. Many makers are only just able to jog along, since they have never taken the trouble to inquire where they are wrong. Often the work is left to a member of the family, ill equipped for it. Then there is want of enterprise as between makers and dealers. People who pay for bad Gorgonzola would sooner pay for good Stilton if only they could get it.

The Cotton Outlook.—It is, perhaps, unlikely that the coming cotton season will be as good both as to demand and profits as that of the last two years, but the prospect at this moment is not discouraging. Presuming upon reasonable prices for cotton, the volume of trade is likely to be large, and probabilities point to a reasonably low price, which would be better both for the mills and the weaving sheds than any other. There is a large carry-over, not only in the visible supply, but also in the hands of spinners. Mr. Thomas W. Elliston, on August 12th, estimated Continental spinners stocks at 1,432,000 bales of all kinds of cotton, or fourteen weeks reserve supply. The estimated English reserve is 516,000, or about seven weeks supply. The carry-over in Europe will be by far the largest for years past, and should have a sobering influence upon the course of prices. As to the probable size of the crop it seems certain that the acreage in America is unusually large. The Bureau says 30,060,000 acres, or 2,000,000 more than in the big crop year of 1905. The *Financial Chronicle* says 33,079,000 acres, and other authorities put it at a still higher figure. The crop met with a cold and wet spring, and much land had to be replanted, some more than once. But the weather reports since the beginning of June have not been unfavourable. Generally the plant is said to be small but heavily planted. Given favourable weather in the ensuing weeks the crop bids fair to be a good average with less low cotton and more good middling relatively to the size of the crop than in the past season. The proportion of high grade promises to be at least an average. The prospects of the Egyptian crop, too, are very favourable. The Alexandrian Produce Association has published a statement of the acreage of this year's crop, which shows a wonderful increase, no less than 67,000 feddans in Upper Egypt, and 29,000 in the Delta. The promise of a record crop has checked buying at Alexandria, and purchases are not stimulated even by the concessions of cultivators, who are said to be offering their lint at prices in considerable disparity with printed quotations. It looks, therefore, as if there will be no lack of raw material this year. As to how profitable the business will be to the spinner and manufacturer, much will depend upon how far the demand can absorb the products of the large increase of machinery now at work and getting to work at home and abroad.

Shellac.—Three or four years ago, the price of shellac, which is used in large quantities by hat

manufacturers at Denton, Stockport, Hyde, and other places round Manchester, was about one-third of what it is to-day. The reason for the rise is doubtful. It has been attributed to the growing demand of the electrical trade, and to the increasing use of high-grade varnishes; but these explanations seem inadequate, for if it be true that the demand increases rapidly every year, it is equally true that the supply seems to increase *pro rata*. There is reason to believe that the standard of purity in the supplies is lower than formerly. India is shipping large quantities of shellac, but it is complained that this season almost every quality has been largely adulterated with resin and other gums. The two principal varieties of shellac are "button" and "orange" lac. Button lac is made in flat cakes, more or less circular in form. Orange lac is also used extensively in the manufacture of varnish. It is usually met with in thin, shivery flakes, and is much easier to judge as to quality than the other.

A New Butter Process.—A new process for the better preservation of butter is on view. Bacterial examination of the action of carbonic acid on cream suggests that it prevents the development of noxious bacteria. Cream and butter turn bad from the action of oxygen in the air, and bacteria contained in the air. In their ordinary treatment, the water in them contains oxygen which is mixed all over the butter and assists in the oxidation of the fatty matter. In the new process the oxygen is displaced by the carbonic acid, and it is claimed that no oxygen remains in the butter, and also that the water contained in it is carbonated and so keeps the butter free from oxidation or bacteria which cannot live without oxygen, and are detrimental to its quality. Chemical preservatives detrimental to health are said to be absent from the process, and it is claimed for it that it is a very simple, cheap, and effective treatment. The process is at least interesting and novel. Theoretically it appears correct, and unless in practice there turn out to be objections to it, or difficulties in working the process, it should prove of value to those connected with the dairy industries. The matter is hardly yet beyond the experimental stage, but there is a probability of the process being tried on a commercial scale by some manufacturers of butter.

GENERAL NOTES.

JAPAN.—In his report on the trade of Japan (Cd. 3283), Mr. Harrington, Acting Commercial Attaché to His Majesty's Embassy at Tokio, refers to the spirit of speculation that swept over Japan in 1906 and early in the present year, illustrating it by the subscriptions for the shares of the South Manchurian Railway Company. One hundred thousand shares, totalling 20,000,000 yen (£2,040,000) were offered for subscription. Arrangements were made by which the receiving banks retained the deposits on application, paying interest therefor, while at the same time the banks were able to lend money for application at a higher rate of interest. Thus were persons with inadequate means able to apply for shares, and, in anticipation of over-subscription, excessive quantities of shares were applied for. The result was that some 12,000 persons made application for no less than 106,730,000 shares. This number would represent some 21,346,000,000 yen, or not far short of the largest estimate hitherto made of the total capitalised wealth of Japan. Towards the end of the year an extraordinary appreciation took place in the shares of most companies, due in many cases to speculation on futurity shares, *i.e.*, on shares which were expected to be issued as the result of increases of capital, and which were considered certain to be above par like the original shares. Eventually, in January and succeeding months, everything was forced down, causing great depression in the money market and business generally. Several computations, says Mr. Harrington, of the total wealth of Japan have been made. The most recent, and possibly the most satisfactory, estimate places the capitalised wealth at approximately £2,311,000,000, excluding Formosa.

SWEDISH FISHERIES.—The Swedish Government is doing a good deal to develop the sea fisheries of Sweden as well as the river and inland fisheries. The nation appears to be realising the great importance of the proper care and administration of the fisheries as well as of the industries connected therewith. In order to assist the seaport population and fishing enterprises the Government has placed a comparatively large sum at the disposal of the local authorities upon very easy terms, and the fishermen have largely availed themselves of this opportunity for the purpose of improving their craft and gear. Mercantile associations also have benefited by support from the Government in this direction. Thus a herring fishing expedition to the Islands has obtained a grant of money from the State which has enabled those interested to provide a complete and proper outfit. In his report on the trade and commerce of Gothenburg (3283-167) Mr. Consul John Duff says that the purse-seine which was introduced into Sweden some 20 years ago, and at first received by the fishing population with distrust, has gradually made its way, and with the modern motor-boat as auxiliary, the outfit of to-day's herring fisher may be looked upon as perfected. The rational lines upon which the fisheries are now worked give those occupied in the industry a return far beyond that of the fisheries of former times, even in the bright days of the great herring fishing. The ancient stock of "poor fishermen" who with their line, net, and small gear, gleaned a precarious living out of the sea, will soon be a memory of the past.

Journal of the Society of Arts.

No. 2,861. VOL. LV.

FRIDAY, SEPTEMBER 20, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

"OWEN JONES" PRIZES FOR INDUSTRIAL DESIGN.

This competition was instituted, in 1878, by the Council of the Society of Arts, as trustees of the sum of £400, presented to them by the Committee of the Owen Jones Memorial, being the balance of subscriptions to that fund, upon condition of their expending the interest thereof in prizes to "Students of the Schools of Art who, in annual competition, produce the best designs for Household Furniture, Carpets, Wall-papers and Hangings, Damask, Chintzes, &c., regulated by the principles laid down by Owen Jones." The prizes are awarded on the results of the annual competition of the Board of Education, South Kensington.

Six prizes were offered for competition in the present year, each prize consisting of a bound copy of "The Leading Principles in Composition of Ornament of Every Period," from the Grammar of Ornament, by Owen Jones, and a Bronze Medal.

The following is a list of the successful candidates :—

Bloom, Dorothy, School of Art and Design, Nottingham.—Design for a Stencilled Hanging.

Crompton, Oswald, School of Art, Sunderland.—Design for Tapestry.

Newman, Samuel, School of Art, Macclesfield.—Design for a Woven Silk Hanging.

Powell, Ellen, School of Art, Stroud.—Design for Printed Muslin Hangings.

Sumner, Philip, School of Art, Macclesfield.—Design for a Tapestry Hanging.

Willock, John. S., School of Art, Manchester.—Design for a Stencilled Hanging.

The next award will be made in 1908, when six prizes will be offered for competition.

SECTIONAL COMMITTEES.

APPLIED ART SECTION COMMITTEE.

The following is the list of the Applied Art Section Committee, as appointed by the Council :—

Sir Steuart Colvin Bayley, K.C.S.I., C.I.E. (Chairman of the Council).
Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D. (Chairman of the Committee).
Sir William Abney, K.C.B., D.C.L., D.Sc., F.R.S.
George Frederick Bodley, R.A.
Sir William Bousfield, M.A., LL.D.
Prof. A. H. Church, M.A., F.R.S., F.C.S.
Arthur Crozier Claudet.
Alan S. Cole, C.B.
Sidney Colvin, M.A.
Walter Crane, R.W.S.
Henry Hardinge Cunynghame, C.B.
Cyril Davenport, F.S.A.
Lewis Foreman Day, F.S.A.
Alfred East, A.R.A.
Arthur Evans, F.R.S.
Hon. Sir Charles W. Fremantle, K.C.B.
William Gowland, F.S.A.
Gerald C. Horsley, F.R.I.B.A.
Thomas Graham Jackson, R.A.
Arthur Lasenby Liberty.
Seymour Lucas, R.A.
Sir Edward J. Poynter, Bart., P.R.A.
Halsey Ralph Ricardo, F.R.I.B.A.
William Edward Riley, F.R.I.B.A.
Alexander Siemens.
A. B. Skinner, B.A., F.S.A.
R. Phené Spiers, F.R.I.B.A., F.S.A.
Hugh Stannus, F.R.I.B.A.
H. H. Statham, F.R.I.B.A.
Carmichael Thomas.
Professor John Millar Thomson, LL.D., F.R.S.
Sir Thomas Wardle.
Sir Aston Webb, R.A., F.R.I.B.A., F.S.A.
Henry B. Wheatley, F.S.A. (Secretary).

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

GOLD MINING AND GOLD PRODUCTION.

By Prof. John Walter Gregory, D.Sc., F.R.S., F.G.S.

Lecture II.—Delivered February 4, 1907.

II.—Gold-bearing Lodes.

The ideal of mining being the extraction of ores and minerals at the minimum of cost, mining operations should be guided by the best available evidence as to the underground courses of the ore deposits, in order to avoid the waste of search in wrong directions; and the miner should use the best available clues as to the depth to which a lode is likely to extend and as to its variations in value with depth, so that the mining equipment selected may be economically suitable to the work it will have to do. Hence comes the practical value of theoretical questions as to the geological characters and genesis of ores.

Alluvial gold is detrital in origin: at one time the belief was popular that the gold grains and nuggets in gravels grew there from percolating solutions. This view has a strange fascination over practical alluvial miners; and it is still occasionally advocated in mining literature.

Alluvial gold is derived from the destruction of gold-bearing lodes, and when the alluvial deposits of a field are exhausted the miner turns his attention to the lodes from which the detrital gold was derived. The work changes from alluvial to lode mining; and the gold in lodes is so constantly associated with quartz, that all gold lode-mining is sometimes spoken of as quartz-mining. Gold is, however, found, though usually only as a subsidiary constituent, in ores of silver, copper, lead and zinc.

The Term "Reef" and its Opposite Meanings.

The quartz sheets in which gold occurs are called lodes, reefs, or veins. In accordance with the practice of Australia and South Africa, the generally adopted British term is reef; but that word must be used with caution, for it is used in different mining fields with exactly opposite meanings. On one field, the "reef" is the gold-bearing ore; on an adjacent field the reef, on the contrary, is the barren rock in which the ore deposits are included.

The responsibility for this confusion rests with Australia. During the first half of the last century, sheets of metalliferous ores were known as veins or lodes. Thus the Cornish mines derived their ores from the Standard Lode, Daniell's Lode, &c. From Cornwall, the term lode was introduced into America, and thus the great gold-quartz veins of the Sierra Nevada received their name of the "Mother Lode" of California, and the most famous ore deposit of Nevada is known as the Comstock Lode, not the Comstock Reef. The term reef was introduced into mining in Australia. The miners there began work on the alluvial deposits, and excavated them down to the underlying bed rock; then, in accordance with a habit of using nautical terms acquired in the long voyage to Australia, the miners said they had struck a reef; for striking the bed rock was as fatal to their mine as striking a submerged reef at sea would have been to their emigrant ship. So the bed rock was called the reef, a perfectly correct use of the term. When mining proceeded to the gold-quartz veins, they were described as reef-quartz, to distinguish them from the quartz pebbles of the alluvial deposits. From speaking of the quartz as "in the reef," the passage was easy to calling the veins "quartz-reefs," and thus the term reef passed from meaning barren material into a synonym for a lode. The term is still used in its original meaning in alluvial mining. Thus, the "reef drive" of a deep lead mine is the drive in the underlying, barren bed rock. It is probably too late to get rid of the double use of the word reef, and it is, therefore, important to remember that the term is ambiguous owing to its local reversal of meaning. The older name, lode, is not open to this objection.

Classification of Gold-bearing Lodes.

Gold is found in lodes of many different types. The most typical gold-bearing lodes consist of sheets or masses of quartz, traversing barren rocks, which are technically named the "country." The lodes often occur in slates, which are readily worn away, so that the harder, more resistant quartz may stand above the surface in long, narrow walls.

Quartz mining in Australia was begun by a party of French miners chipping out the pieces of quartz showing visible gold from such an outcrop at Black Hill, Ballarat, and then crushing the fragments with hammers. After the outstanding part of a lode has been removed, the lode is followed down and quarried

by an open-cut. The rest of the lode, which is too deep for open working, has to be reached by a shaft and underground mining.

A lode may have parallel, well-defined sides, and such lodes are often of great length and depth. But, unfortunately for the quartz miner, even a thick lode may break up into thin quartz veins running irregularly through the country rock; or it may taper out and cease altogether. Vein quartz also occurs in lenticular masses, known as "makes," "bulges," or "blows"; so that what appears to be a thick quartz sheet may be only a part of a lens-shaped block, which, when followed downwards, soon becomes thinner and disappears. A thick quartz mass may be reduced to a mere string of quartz; it too may disappear, leaving only a narrow empty "lode track" which may, however, lead to another mass of quartz.

A lode may be formed by the filling of a fissure caused by the shrinkage of the rocks, or by a fault. The fissure may open above to the surface, and may be continuous across several rocks; or it may be a crack confined to one bed of rock, in which case it is called a gash vein. The quartz may occupy the whole width of the lode; or it may be deposited in the spaces between broken fragments of the adjacent rocks which have fallen into the fissure, or been torn off the walls. Some quartz lodes have sharply defined margins, but in others there is a gradual passage from the lode to the older rocks beside it; and these lodes are sometimes so thick, and occur at depths where the pressure is so great, that large fissures could not have remained open; moreover, projecting tongues or loose blocks of slate occur floating in the quartz in positions they could never have retained in an open space. Such lodes cannot, therefore, have been formed in fissures; many geologists were accordingly persuaded that quartz veins are of igneous origin; the quartz was thought to have been forced up from below in a molten state, to have pushed the rocks apart, and at the same time been injected into any adjacent cracks. Quartz veins were thus regarded as intrusive quartz dykes. This theory is, doubtless, true for a few quartz veins. There are igneous quartz dykes which are due to all the basic constituents in a molten rock having crystallized out, leaving the acid material to flow on as molten silica. They are the ultra-acid residues from ordinary quartz-felspar dykes. But I have seen no case in which quartz of igneous origin is payably auriferous. The economically important gold-quartz lodes have had quite a different origin from such quartz dykes. The thick lodes are due to the slow replacement of slate or sandstone, particle by particle, by quartz. This process forms thick sheets of quartz, without the necessity for the existence of open spaces. Such lodes are described as metasomatic or replacement lodes, and more and more of the chief quartz lodes are being recognised as of this origin.

Quartz veins vary not only in mode of origin but in form, and in their relations to the surrounding rocks. The veins may run down as pipes in "pipe veins," as continuous sheets in "fissure veins," as a network of quartz enclosing broken masses of mullock along faults, or as irregular ramifications through a belt of shattered country between two powerful faults, or in numerous veinlets in the fractures beside faults, or as successive horizontal platforms or steps, or as "bedded veins" parallel to the bedding in the surrounding rocks.

The most useful classification of gold lodes rests on the nature of the rock in which they occur. The chief groups of lodes, arranged according to their character, are as follows:—

(1). Gold-quartz lodes in sedimentary rocks.

(2). Gold-quartz lodes in foliated igneous rocks.

(3). Mineralised belts of rock traversed by quartz-veins and veinlets.

(4.) Quartz lodes in association with propylitic igneous rocks, especially diorites.

(5). Gold-quartz lodes in non-schistose volcanic rocks.

(6). Gold occurring as a by-product in masses of pyrites or other sulphides, with their overlying rich secondary gossans.

(7). Gold-quartz ores formed by infiltration of gold into sediments, especially limestones and dolomites.

(8). "Banket," *i.e.*, ancient auriferous conglomerates, according to some authorities, should also be included among lodes.

(1).—Gold-quartz Lodes in Sedimentary Rocks.

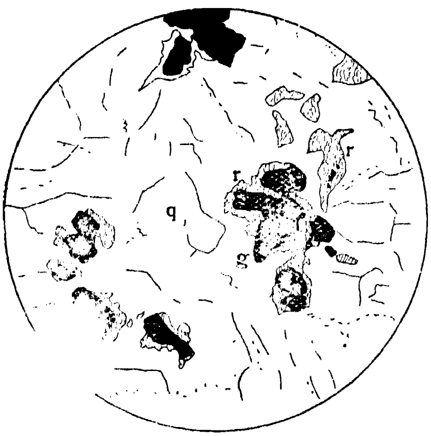
Of these various classes of gold ores, the most typical are the gold-quartz lodes and veins found in sedimentary rocks. They are, as a rule, found in slates, but they also occur in quartzites and limestones. The quartz is of the variety known as vein-quartz, which has been deposited from water. The lodes may consist of a sheet or pipe of quartz, of an irregular net-work of quartz-veins, of isolated lens-shaped masses, or of series of quartz

veins ramifying through a belt of mineralised country.

The simplest type of these gold-quartz lodes are simple fissure veins Fissure veins often divide into many branches which are connected by cross veins, and thus form a complex lode. Many important lodes are found along faults, and contain broken fragments of the country rock; they are often called "brecciated lodes," from the abundance of angular masses of mullock included in them.

Where the country beside the lode is much fractured, the vein-quartz may not be limited by sharply defined boundaries, and there is a

Fig. 8.



A Thin Section of Gold-Quartz Ore with Free Gold. Sumpter, Oregon (after Lindgren) × 28 dia, q = quartz, g = gold, r = roscoelite.

gradual passage from the quartz into slate beside it. The slate has been silicified, its original constituents having been removed and replaced by silica, till at length part of the rock is converted into ordinary vein-quartz. It is often impossible to draw a line between a simple fissure-vein formed along a fault or a joint and a replacement lode; and some lodes were first formed as fissure-veins, and have been enlarged by the replacement of the rock on the walls.

Lodes along faults have a tendency to develop into alternate masses or lenticles of quartz connected by a thin lode-track. The masses fill the spaces formed where the two walls of the fault are forced apart owing to the meeting of projecting surfaces.

Bedded veins, on the other hand, are often remarkably regular, as they follow the bedding planes. Where the rocks have been folded into alternate arches and troughs, the quartz may be deposited in thick bands along the tops of the arches and in the bottoms of the troughs, as the pressure in those positions was less than on the sides of the folds. Thus have been formed saddle lodes and inverted saddle lodes.

The most famous representative of all the lodes in sedimentary rocks is the great "Mother Lode of California." It is not one continuous vein, but a belt of many parallel and branching veins, which increase and decrease in thickness, and disappear and reappear on the same line. This complex lode can be traced for 112 miles north and south along the Sierra Nevada. It occurs in slates and sandstones of Carboniferous and Mesozoic age, which have been penetrated by great masses of igneous rock, known as granodiorite. The fracturing of the earth's crust and heating of the area during the invasion of these igneous rocks rendered possible the ascent of the gold-bearing solutions.

The gold-quartz lodes of Victoria include many examples of this group, most of them are in Ordovician slates, and many of them were formed before the Carboniferous period, so that they are much older than the lodes of California. The slates in Victoria have also been invaded by granodiorites and allied igneous rocks. Many of the chief gold lodes occur in the neighbourhood of these intrusive masses.

The great gold-quartz lodes of Ballarat West are typical examples of continuous sheet-like lodes, and the mines have followed shoots of gold ore down to the depth of 2,300 feet. The adjacent mines of Ballarat East, on the other hand, work lodes formed as an irregular network of quartz-veins ramifying irregularly through slates and sandstones. Saddle lodes are best developed in the Bendigo Goldfield in Victoria, and near Halifax in Nova Scotia.

(2.)—Gold-quartz Lodes in Foliated Igneous Rocks.

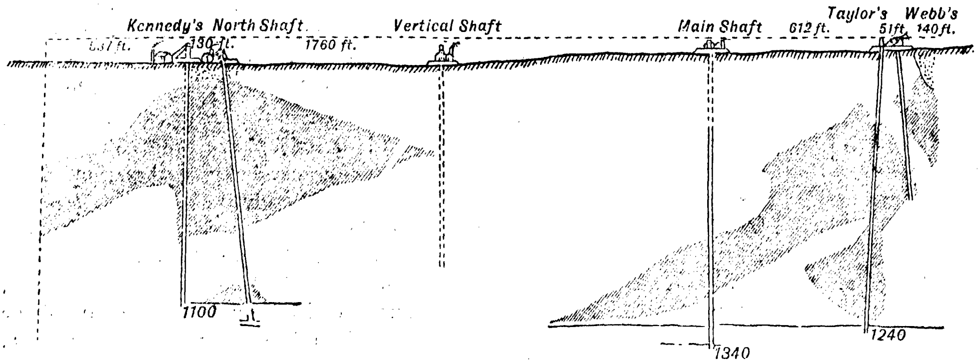
Gold-quartz lodes in igneous rocks which have been altered into schists are usually less regular than those in sedimentary rocks. The lodes are very variable in thickness, while their walls are often extremely irregular and indefinite. This is a natural consequence of the fact that igneous rocks, owing to their more complex chemical composition and higher proportion of soluble constituents, are less stable than sedimentary rocks, which are composed of simpler and less changeable materials. Hence most of the lodes found in

schistose igneous rocks are in the main replacement lodes.

Schistose igneous rocks, however, often preserve a more uniform composition in depth than sedimentary rocks, and it is, therefore, not surprising that the lodes and ore shoots in them often continue to great depths.

nated with auriferous sulphides are of great importance from their vast size, although the ores are usually of low grade. The lodes often occur in granite, using that name in its popular sense. Sometimes the quartz veins are so thin and pass so imperceptibly into the quartz grains of the country rock, that they are easily overlooked, and thus the gold has been described as a primary constituent of the granite.

FIG. 9.



LONGITUDINAL SECTION THROUGH THE NUNDYDROOG GOLD MINE, showing the dip and form of the Ore-Shoots. (After Hatch.)

Goldfields on schistose igneous rocks may be illustrated by Kalgoorlie with its famous Golden Mile. The lodes have been formed by replacement. They are generally in altered amphibolites, but sometimes the mineralisation passes outward into the granitic rocks beside the schists. The Kalgoorlie ores are very complex and refractory, and the absence of water placed great difficulties in the development of this field. But water is now pumped to it from the coast, through a pipe 350 miles long, and the ingenuity of the Australian miners has overcome the metallurgical obstacles to the extraction of their gold. The lodes have been followed down to the depth of over 2,000 feet, where the ores, though poorer than near the surface, still maintain rich values.

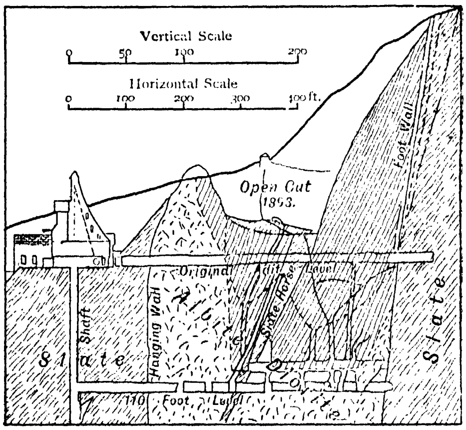
A simpler type of lodes belonging to this group is developed in Mysore in India, for the hornblende schists of the Kolar Goldfield, according to Holland's description, are altered igneous rocks. The shoots have been followed with well maintained values, down to the depth of 3,000 feet. The gold mines in the Selukwe and Sebakwe districs of Rhodesia occur in a field of which the structure in many respects resembles that of Mysore.

(3).—MINERALISED GOLD-BEARING BELTS.

Lodes which consist of mineralised belts of rock seamed with gold-quartz veins or impreg-

The simplest of these lodes are dykes of a variety of granite known as beresite, found at

FIG. 10.



SECTION ACROSS THE ALASKA TREADWELL MINE. (After Becker.)

Beresov in the Urals. Representatives of this group of greater economic importance are worked in many parts of the world in granitic rocks, such as the Alaska Treadwell Mine, on Douglas Island, off the coast of Alaska. Its ore is a mineralised "granite" or albite-

diorite; it is of low grade, containing gold to the value of 10s. 10d. to the ton, but the quantity is enormous; the mine is worked for a length of 3,500 feet, and the ore is crushed by a mill of 540 stamps. Owing to the large scale of the operations, and the use of water-power, the ore is treated for a total cost of 5s. 4d. per ton. The Jumbo Mine in Rhodesia represents another of these low-grade broad bands of "granite" impregnated with gold-bearing sulphides.

A second series of mines in mineralised belts of rock includes those in quartz-schists and quartzites. The most famous of them is the Homestake Mine in South Dakota, at present the greatest gold mine in the world. The country rock is a wide band of quartzite, seamed in all directions with gold-quartz veins. The lode has been mined for a width of 550 feet; the ore is crushed in three mills having a total of 1,000 stamps, and its gold is recovered by simple cyanidation. The Wanderer Mine in Rhodesia is another low grade mine with similar geological characters. It is a mineralised band of iron-bearing schistose quartzite.

The future of the gold mines of this group depends upon whether the gold will be confined within narrower limits in the deeper levels of the lodes. If the ore keeps of the same width and low grade as near the surface, the limit of profitable mining will be comparatively shallow, although the Homestake Mine has already a shaft down to the depth of 1,400 feet.

(4).—Lodes connected with Propylitic Diorites.

The next important group of gold-quartz lodes are those associated with various dykes of igneous rock, and especially with diorite. This name is, however, given to many rocks which would not be accepted as diorite by a particular petrographer; but most of them are allied in chemical composition to true diorite, though, owing to differences in the conditions of their consolidation, they may differ in their mineral composition and structure. Many of the so-called diorites are hornblende-porphyrites, while many of the massive representatives are called grano-diorites, being intermediate in composition between granite and diorite.

The lodes of this group are intimately and usually directly associated with the adjacent diorite. The lode and the diorite dyke may be in close contact, or, perhaps, occasionally separated by a block of the country rock. This type may be illustrated by the Long Tunnel and the Long Tunnel Extended Mines at Walhalla in Victoria. There the chief lode —the Cohen Lode—has been worked in more or less constant company with a diorite dyke to the depth of 3,100 feet.

In other mining fields the lodes are confined within the diorite; they then often consist of horizontal layers or floors of quartz, arranged like the rungs of a ladder. The dyke itself may be nearly vertical, while the quartz floors extend across it horizontally. Such "ladder lodes" are due to the igneous rock having cracked by contraction as it cooled; silica dissolved from the adjacent rocks was deposited as vein-quartz in the contraction spaces. Where the diorite happens to be firmly attached to the slates beside it, the fissures caused by the shrinking of the dyke extend into the slates; and in such cases, the quartz veins extend beyond the dyke, to which, as a rule, they are confined.

In most gold-fields where the lodes are in contact with diorite dykes, there has been lively controversy as to whether the dykes determine the amount of gold in the adjacent lodes. Very contradictory evidence has been adduced, which is, however, explained by the microscopic study of the rocks. Where the dyke is unaltered it appears to have had no effect upon the gold contents of the lode. But where the diorite has undergone the change known as propylitization, the adjacent rocks are auriferous. This change consists in the alteration of the original constituents of the diorite; the felspars have been changed into a secondary mosaic of quartz, felspar, and zoisite; the hornblende or other ferro-magnesian mineral has been converted into grains of epidote and chlorite. This propylitic action is a secondary process, which happened after the intrusion of the igneous rock, and usually affected both the diorite and the adjacent sediments. It is to this secondary action, and not to the diorite itself that the gold is due. The propylitic change can be certainly determined only under the microscope, but when its action has been thus detected, the change can usually be recognised in hand specimens of the rock. Among well-known mines in propylitic diorites are the gold mines of Chemnitz in Hungary, the famous Comstock Lode in Nevada, the Ayrshire diorite dyke in Rhodesia, and the A1 Mine at Gaffney's Creek, Victoria.

(5).—Gold Lodes in Normal Volcanic Rocks.

Gold ores in association with non-schistose volcanic rocks are of great importance in various parts of the world, and some of them have been formed in comparatively recent times. These volcanic rocks differ from the schistose igneous rocks as they are younger, and have not been crushed into schists; and they differ from "diorite" as they are essentially volcanic rocks, which have been discharged in lava flows over the earth's surface, instead of being subterranean intrusions. The gold mines of this group may be illustrated by three chief types.

Cripple Creek, in Colorado, at present the richest gold-producing locality in America, is perhaps the most interesting. It is the stump of an old volcano, and is situated in the Rocky Mountains, a few miles to the west of Pike's Peak. Its ores are arranged in shoots and chimneys rising through the old volcanic neck. That hot vapours due to volcanic action were present during the introduction of the ores is indicated by the abundance of fluorspar in the lodes. The ores are more complex than those of ordinary gold-quartz lodes, and, as some of the gold is present as telluride, the ores require complex metallurgical treatment. The San Juan Goldfield in south-western Colorado contains vertical lodes traversing a thick series of volcanic rocks and breccias. The ores contain abundant tellurides, as we are reminded by the fact that one of the mining towns in this field is named Telluride.

Fig. 11.

Waihi, the chief gold mine of New Zealand, is situated in a wide volcanic plateau, and is also assigned to this group, but it has some resemblances to the mines associated with the propylitic diorites.

(6).—GOLD IN SULPHIDE ORE MASSES.

Gold as a subsidiary constituent is present in many masses of pyrites and lead ores. In these cases the mines are worked for their copper and lead, the gold being recovered as a by-product. As a representative of this group may be cited the Mount Lyell Mine in Western Tasmania, which was first opened as a gold mine, but subsequently developed as a low-grade copper mine. To a variety of this group belongs one of the most interesting and most discussed gold mines in the world—the Mount Morgan Mine in Queensland. It consisted in its upper workings of a siliceous ore showing such clear evidence of deposition from solution that it was originally described as a geyser deposit. The gold in the uppermost part or gossan of the lode had been deposited from solution, and its separation from other metals had been so thorough, that Mount Morgan gold still holds the record amongst the mines of the world for the purity or "fineness" of its gold. Some of it contained as much as 997 parts of pure gold in 1,000 parts of native gold. It is now generally understood that the cap of this remarkable mine is only the altered silicious gossan of a great mass of pyritic ore, which is now being worked. The Mount Morgan Mine after being famous for the exceptional richness of its gold ores, has begun a fresh period of usefulness as a low grade copper mine.

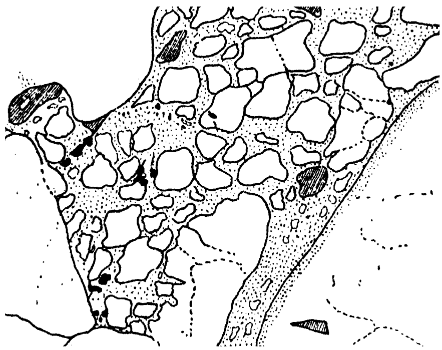
(7).—GOLD IMPREGNATIONS IN SEDIMENTARY ROCKS.

Gold ores due to the infiltration of gold into sedimentary rocks are formed mainly in quartzites, limestones, and dolomites. The solutions have usually risen up faults or beside dykes, and have then spread horizontally along a bed of permeable rock. One of the best established cases is that of the siliceous gold ores of South Dakota, near the Homestake Mine; the gold solutions have come up along the edges of dykes, and long vertical cracks known as "verticals." The ore bodies thus produced are compact and well defined.

(8).—AURIFEROUS BANKET.

Ores due to the infiltration of solutions into sedimentary rocks are comparatively unimportant, unless, as is asserted by a prevalent view, the gold of the Rand banket is of this origin. The ores of the Rand goldfield consist of beds of conglomerate or pebble reef, known as banket; this rock is charged with pyrites, and is often rich in very fine gold. (Fig. 12.) The banket or pebble-

FIG. 12.



BANKET. SECTION OF SPECIMEN OF THE MAIN REEF LEADER, containing 1,383 dwt. of gold per ton, × 25 dia. The section includes part o one large pebble of quartz and of two smaller pebbles; the rest consists of a fine quartz grit. The interspaces between the quartz grains are occupied by a dusty material composed mainly of minute flakes of sericite and kaolin, with small crystals of chloritoid. The large shaded areas are pyrites; the grains in solid black are gold.

reef was at first regarded as an old marine shingle beach, in which the gold was of alluvial origin. Evidence was soon forthcoming to show that this was not a full explanation; and it was suggested that the gold had been precipitated from solution in sea water, and then mechanically concentrated in the coarse conglomerates. This view is now only of historic interest. The theory which has been most generally accepted in recent years is that the gold has been introduced in solution and deposited in the conglomerate as in an ordinary gold-quartz lode.

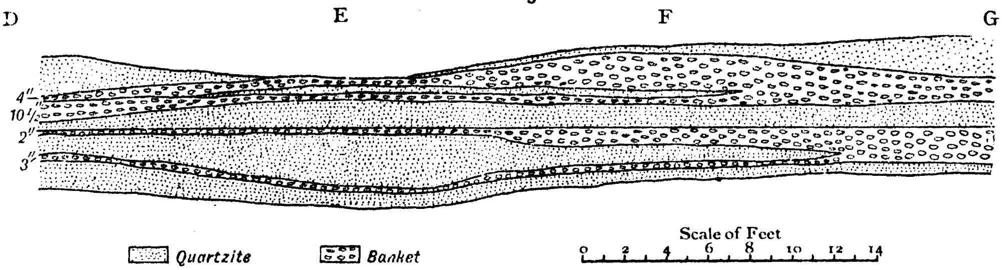
There is no time to go into this question, which I hope to treat shortly elsewhere; but the differences between the ores of the Rand and ore of which the gold has unquestionably been introduced in solution, and the many striking resemblances between the distribution of the gold with that of placer deposits, lead me to agree with the authorities who hold that the pebble-reef is an old placer, in which the gold was of alluvial origin, but has been dissolved and redeposited *in situ*.

THE MICROSCOPE IN MINING GEOLOGY.

The characters of the different types of gold ores may best be recognised under the microscope. The use of the microscope in mining geology is of the highest value, and to it we owe the great progress which has been made during the last few years in the explanation of the genesis of ores. The evidence thus obtained, as to the origin of the ores gives, moreover, most illuminating clues to their distribution. Chemical analysis often detects no difference between ores of fundamentally different natures. A siliceous bedded ore and the vein quartz of a vertical gold-quartz lode may have identically the same composition. The chemist could recognise nothing in a specimen from the former inconsistent with its having come from a lode, which might carry its ore shoots down to vast depths. The microscope, however, would at once show that, though such a rock may be entirely composed of silica, it may have been formed by the silicification of a bed of dolomite; and any prudent miner would be prepared to find that the ore was either limited to that bed or completely changed its character if the lode passed into another rock.

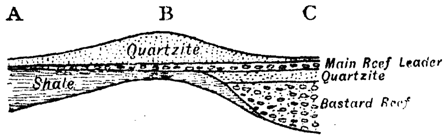
The microscope, moreover, can be of invaluable assistance to the mining engineer in detecting salting. Most of the commonest and most successful tricks of the salter can be detected by the study of the samples under the microscope.

FIG. 13.



SECTION ALONG 45 FEET OF THE SOUTH REEF IN THE NEW GOCH MINE, JOHANNESBURG, showing that the banket occurs irregularly interbedded with layers of quartzite. At D the section includes 4 beds of banket, in descending order, 4 inches, 10½ inches, 2 inches, and 3 inches thick, and of value respectively of 25 dwt., 5 dwt., 2 dwt., and 16 dwt. At E the 4 beds of banket are in descending order 4 inches, 4 inches, 3 inches, and 2 inches thick, and their values respectively are 19 dwt., 0 dwt., 9 dwt., and 81 dwt. At F the 4 beds of banket are in descending order, 20 inches, 5 inches, 11 inches, and 3 inches thick, and their values respectively are 2·6 dwt., 1 dwt., 6 dwt., and 19 dwt. At G the banket is in two beds, of which the upper one is 12 inches thick, and contains 12 dwt., and the lower is 21 inches thick and contains 4·6 dwt. Scale 1 inch = 5 feet.

FIG. 14.



SECTION ALONG 20 FEET OF THE MAIN REEF LEADER IN THE NEW GOCH MINE. The Leader increases from 2 inches thick at A, where its value is 36 dwt. per ton, to 4 inches thick at C, where its value is 162 dwt. per ton; at B the value is 16 dwt per ton. At A the Leader lies between beds of quartz, etc., and shale; the shale thins out at the other end of the section, and is replaced by a bed of Bartard Reef which at C is 36 inches thick, and has the value of 1 dwt. per ton. The value of the whole stoping widths are A 5½ dwt., B 3·9 dwt., C 30 dwt. Scale 1 in. = 10 ft.

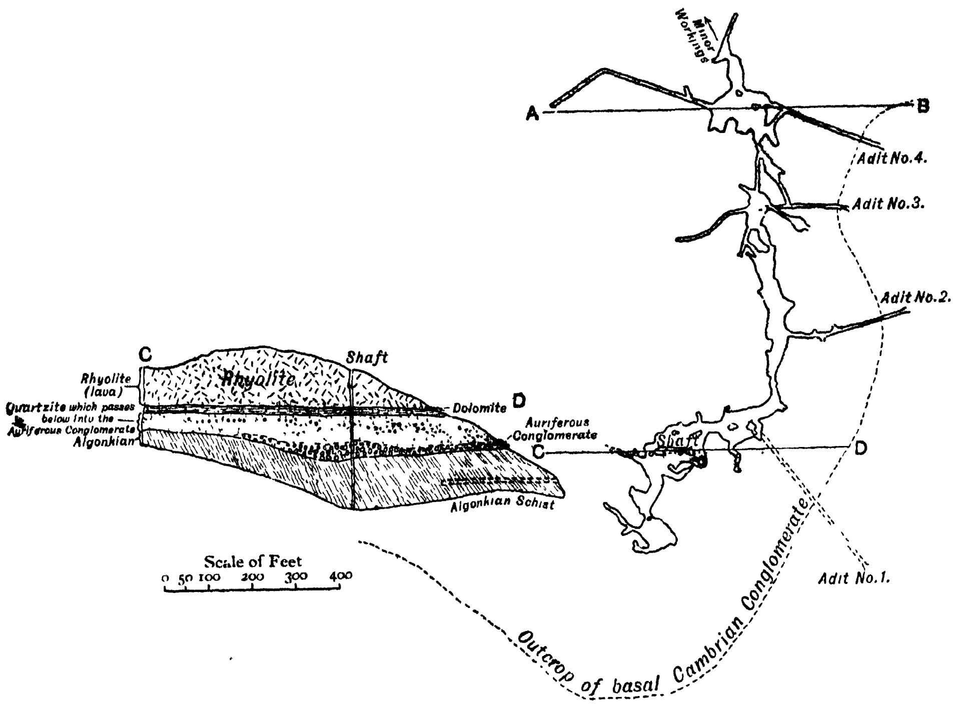
PRACTICAL VALUE OF DETERMINATION OF ORE GENESIS.

It is mainly from its bearing on ore genesis, however, that the microscope is an invaluable aid to the miner. It prevents him from being misled by those false analogies between different mines, which have been the cause of the disastrous failure of so many mining enterprises. The practical value of the determination of how an ore has been produced is now being generally recognised, and it may be illustrated by the following example.

At Bendigo the quartz veins were found in big "V" shaped masses, which rapidly thinned out below till they disappeared. The quartz was in isolated blocks which appeared to be distributed irregularly through the country rocks. The quartz blows exposed on the surface disappeared at slight depths; so it was thought that the field was practically worked out, all its lodes being shallow. The gold yield fell from 500,000 ozs. a year to only similar positions recur one below another in vertical series.

Where a saddle reef is found, another saddle reef will probably occur below it, between some deeper layers of sandstone and slate. So the discovery of the lower saddles of quartz is not left to chance; their distribution instead of being capricious as had been feared, is quite regular; and when one saddle has been exhausted, a deeper reef may be found

FIG. 15.



PLAN AND CROSS SECTION OF THE HAWKEYE-PLUMA MINE, in the Gold-bearing Cambrian Conglomerate of S. Dakota. (After J. D. Irving.) The deposit is in an ancient river placer.

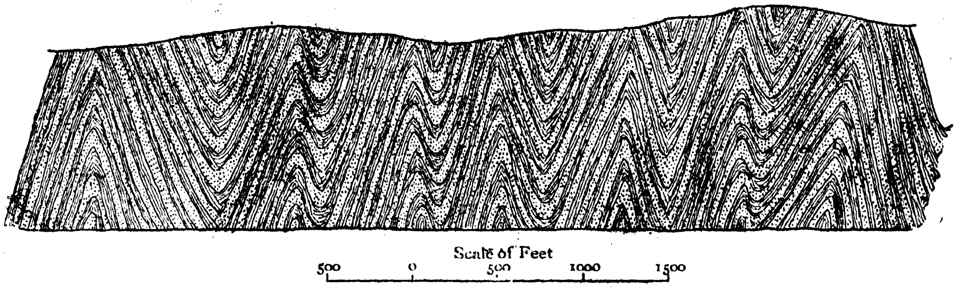
137,964 ozs. in 1890. It was noticed, however, that many of the quartz veins were parallel to the bedding of the slates and sandstones of which the goldfield is composed, and that neighbouring quartz veins sloped in opposite directions. The wedges of quartz were, in fact, only the tips of arch-shaped folds of quartz, each of which rested on an arch of slate, like a saddle on the back of a horse. So they were called saddle reefs. A saddle reef was often found between a band of sandstone and of slate, on the summit of an arch-like fold; and as the country consists of alternate layers of slate and sandstone folded together, beneath it by sinking along the line of what is called "centre-country." Thanks to the guidance of this principle, the Bendigo Goldfield has had a new lease of life; it is the most prosperous of Victorian goldfields, and, instead of its mines being all quite shallow, they have been worked to the depth of 4,250 feet, and are the deepest mines in the world working gold-quartz lodes.

The neighbouring goldfield of Ballarat furnishes another illustration of the valuable guidance to practical mining given by recognition of the genesis of the ores.

In Ballarat East, the hills are composed

mainly of slates, which are seamed in all directions by quartz veins; so irregular are they, that the miners declared that there were no true lodes in the goldfield—only a tangle of useless veins. The quartz in these veins was mostly barren, but the miners were tempted again and again to prospect them, as they had certainly yielded the great gold nuggets for which Ballarat is famous. The efforts as a whole were unsuccessful, but the miners were occasionally rewarded by the discovery of rich patches or nuggety masses of gold; the distribution of these rich patches appeared so capricious that it seemed useless to search

FIG. 16.



SECTION ACROSS THE CASTLEMAINE GOLDFIELD. Composed of contorted slates and quartzites, wit which are associated bedded quartz veins developed as saddle reefs. (After W. Baragwanath, Jnr.)

A SADDLE REEF IN THE CARTLEMAINE GOLDFIELD. (After W. Baragwanath.)

for them. But at length the clue to their distribution was discovered. The slates are traversed by numerous secondary seams of chloritic minerals, produced along planes of what is known as slip-strain. (Fig. 18.) The chloritic minerals, when decomposed, give rise to materials which can precipitate gold from its solutions.

Where one of these seams meets a quartz vein, a rich patch of gold often occurs at the point of intersection, whereas a few inches away on either side the quartz is quite barren. The chloritic seam continues beyond the quartz vein, and at its intersection with the next quartz vein there may be another nuggety patch of gold. These narrow seams are found, in fact, to lead to the points where the gold is concentrated in the quartz veins. Hence, as they indicate where the rich gold was found, they are called indicators, and many of the mines of Ballarat East have been worked successfully by following these seams from one rich patch of ore to the next. The whole of the gold in the area is not found on these indicators, for much of it comes from veins and

FIG. 18.

masses of quartz along faults. But in a critical period in its history, the field was saved by the discovery how to use these indicators in the search for the rich nuggety patches of gold.

These instances show the necessity of the detailed geological study of mining fields; for two of the most important goldfields in Victoria, of which one was thought to have only shallow ore-bodies, and the other to have no lodes at all, have been successfully developed since the discovery of the plan of their gold distribution. So long as it was believed that no better explanation of the distribution of the rich gold patches and quartz masses could be given than in the old Cornish mining proverb, "where they are, there they are," the continued success of those fields was impossible. But now that we know "why they are where they are," the Bendigo mines have been carried down till they hold the existing record in depth of gold-quartz mining.

SMALL OCCUPYING OWNERSHIPS.*

The British land system, namely, that of landlord, farmer, and labourer—which meant three separate castes—has broken down in every other country in Europe, has broken down in Ireland, and is breaking down in England. To it is mainly due our startling rural depopulation. Whilst there was an increase of 12·17 per cent. in the total population of England and Wales at the last census, the dwellers in the rural districts had fallen to less than $7\frac{1}{2}$ millions, or to 23 per cent. only of the whole population.

Those who urge that we must rely on trade and commerce for our prosperity are reminded that the greatest wealth of a nation is its producing power, and that, whilst the producing powers of many other undertakings are becoming more and more difficult, those of the land are not half developed. The conclusions urged are:—

(1) That the policy of placing trade and manufactures above agriculture is a wrong one.

(2) That an amount of capital (including the personal labour of the cultivating owner and his family) properly invested in land yields a far greater return to the community than a similar amount invested in commerce and manufactures.

(3) That, if health, physical strength, and an increase of the population are to be reckoned as national assets, agriculture enriches the nation far more than manufactures can.

(4) That the home trade, resulting from the development of agriculture, is larger, more certain, less fickle, and more valuable than the foreign trade.

Agriculture must not be regarded simply as any other trade, but as the basis of all trades. In France, Germany, and other Continental countries a prosperous agriculture and a consequent numerous and thriving rural population are regarded by statesmen as the two great pillars of the State on which the general well-being of the people rests. They are regarded as the true sources of wealth, as the most effective means to secure a wider distribution of wealth, and as the best guarantees for national stability.

Leaving the larger branches of agriculture—the raising of corn, cattle, &c.—and turning to "small cultivation," we observe that we annually import some sixty million pounds' worth of the smaller articles of food, such as butter, cheese, bacon, eggs, poultry, fruit, vegetables, &c., and that these articles might be wholly or mainly produced at home if our land system were what it ought to be. We have the land, and we have the men standing idle or only partially employed. Many country-bred men now employed in the towns would gladly return to the villages (for which they are better fitted) if adequate and reasonable facilities were offered to them.

As to the land, inquiries show that in Great Britain there are some ten to twelve million acres of permanent grass (apart from the land used for hay, rich meadow land, and land unsuitable for the plough) which could be used by small cultivating owners, and this acreage is annually increasing. These ten to twelve million acres of uncultivated land are for the most part a national loss, and on them profitable employment could be found for at least a million of families, growing produce for which there is an almost unlimited demand. To bring the men and land together is the work of the State, acting through a central department as well as through the local authorities.

Where small ownerships have been tried in this country, under the Small Holdings Act, 1892, they have been eminently successful: cases in point are the small holdings in Worcestershire created by the Council of that county. That Act, however, requires amendment, and some attempts were made by the author this year to get it amended, but they were resisted by the Government.

These proposals are only a part of a complete scheme for recreating a peasant proprietary and yeomen freeholders. Attention is called to a Bill (No. 99) before Parliament this year, entitled the "Purchase of Land (England and Wales) Bill," under which it is proposed (1) that present farm tenants shall be able to purchase the freehold of their land on agreement with their landlords or on its coming into the market, and (2) that the Board of Agriculture shall be enabled to purchase land for "small holdings" for persons who desire to buy, and who will themselves cultivate such holdings. The principle of the Bill is the same as that of the Irish Land Act, 1903. If necessary, all the purchase money is to be advanced by the State to the farmer, to be repaid—interest and sinking fund—by annual instalments. The Bill contains provisions against mortgaging, subdivision, and sub-letting, and thus the occupier is

* Abstract of a paper by the Right Hon. Jessie Collings, M.P., read before Section F of the British Association, at Leicester.

safeguarded from these admitted evils to which all owners are often subject.

It is not contemplated that all the land should pass into the hands of cultivating owners—every kind of tenure would no doubt remain—but that "occupying ownerships" ought to be the governing principle of our land system instead of being a mere incident in it.

To facilitate the carrying-out of the suggested scheme of small occupying ownerships, the author strongly advocates: (1) a better system of rural education, and (2) the establishment of co-operation among the cultivators both for the purposes of buying and of selling. But it is pointed out that co-operation is the natural outcome of small ownerships, but is not readily adopted by yearly tenants, who are often here to-day and gone to-morrow. In conclusion it is claimed that the suggested scheme as a whole would go far to solve the grave social problems of the day—the problems of the "unemployed," "housing," "widespread destitution," &c.—and that to pledge the national credit for the purpose of carrying it out would be in accordance with the principles of a sound national and political economy.

THE THAMES BARRAGE PROJECT.

This scheme has now taken a practical shape, a volume of expert studies, and reports on the various aspects from which such an undertaking may be regarded, having been published by Messrs. Swan, Sonnenschein and Company. These reports deal with the project in its general form, as well as with the moot question of dredging as an alternative method of securing greater depth in the Port of London. The subject of silting and infiltration is discussed by Mr. Clayton Beadle, F.C.S.; draining and pumping from the low-lying lands are dealt with by Mr. E. T. Hennell, M.Inst.C.E.; while the sanitary condition of the river occupy the attention of Mr. W. J. Dibdin, Vice-President of the Society of Public Analysts. As to the main features of the proposed barrage, it may be explained that it consists in the construction of a substantial dam across the Thames at Gravesend, by which the waters of the port would be held up to the level of a perpetual high tide, and the undoubtedly grave inconveniences of the present rise and fall would be obviated. It is well known that the Royal Commission on the Port of London, which reported in 1902, recommended various drastic measures with a view to improve the accommodation of the port, and enable it not only to make better provision for the growing maritime trade of London, but also to prevent rival ports like those of Antwerp, Rotterdam, Hamburg, Bremen, &c., from profiting from the defects and drawbacks of London. One of the chief requirements of the present day is of course greater depth of water for the ever-increasing size and draught of steam vessels, and this the Royal Commission recommend should be met by a gigantic scheme of dredging. It is, however, doubtful whether indiscriminate dredging is entirely feasible and safe, and various witnesses who actually appeared before the Royal Commission testified to the extreme care with which dredging operations in the Thames would have to be conducted to avoid collapse or settlement of river walls, houses, and other riparian property. If, therefore, any danger is to be anticipated from dredging a spacious navigable channel not only to Gravesend, but also from Gravesend to London Bridge, the promoters of the barrage project are probably justified in contending that the solution of the problem would be better approached by adding water to the top rather than scraping earth away from the bottom. In homely language, this is what the barrage proposes to do. Access to the port and exit therefrom are to be provided by means of six locks large enough to cope with any ship seeking shelter within the limits of the metropolitan harbour. Once within the barrage, ships and barges would be free to make for any point they might wish to reach, and would not be dependent as now on the flood to enable them to ascend and the ebb to return. There would thus be a better distribution of the river traffic throughout the day and night and the congestion at the lock entrance at the time of high water would be obviated. The cost of the project is estimated at a little above five millions sterling, but this is of course a small sum compared to the thirty millions or so that the purchase of the docks would entail on the ratepayers of London. Among the probable results would be a great diminution in pilotage and towage charges, less time spent in port, and great saving to the dock companies owing to the abolition of locking in and out, which has been estimated to cost £70,000, and also to the abolition of the need for dredging within the docks calculated at from £30,000 to £40,000 per annum.

It seems reasonable to suppose that these economies will proceed directly from the dockisation of the river, and if so they ought to enable the dock companies to lower their charges, which have been so long a matter of complaint on the part of shipowners and merchants.

There is not space here to review in detail all the results anticipated to flow from the barrage, but there is no doubt that, assuming the feasibility of such a project, there would be undoubtable advantages attaching to it, while the drawbacks and difficulties, seem in some cases less serious than anticipated. As to the financial aspect, this must necessarily rest on a very uncertain basis till the entire scheme has been sifted and investigated by experts. What seems to be required is a public enquiry under the Board of Trade where the calculations, arguments, and opinions of the various professional gentlemen whose reports go to make up the present volume, would be tested and examined. Such an enquiry need not obstruct the progress of the Government Bill for creating a Port Authority, which the President of the Board of Trade has announced

his intention of bringing in next session, and at the same time the results of the investigation would prove of great use to the future governing body of the port. The fact that a similar barrage has been planned and nearly finished in the Charles River at Boston, U.S.A., affords some sort of precedent though no doubt the circumstances of the two cities differs greatly.

THE LYONS SILK TRADE.

The amount of silk conditioned at the Lyons Condition House in 1906 was 15,810,871 pounds, an increase of 356,510 pounds over the year 1905. This increase in the quantity of raw silk was not accompanied by a corresponding increase in worked silk (trams and organzines). During the last quarter of 1906 a speculative fever prevailed in the raw silk trade for future delivery, and principally in Asiatic products. The characteristic feature of 1906 was the scarcity of raw material offered in the market, due for the first quarter to the general short crop of 1905. The large crop of 1906 did not, contrary to all expectations, compensate for this shortness. The entire world's product is estimated by the Silk Association of Lyons to be 45,194,300 pounds, compared with 40,785,300 pounds in 1905. Not counting worked silk (silk thread that has been twisted and is ready for the weaver) the imports of raw silk amounted to 15,667,446 pounds. These figures give adequate idea of the actual amount of business transacted in raw silk by Lyons merchants. They have houses in China, Japan, Syria, and Italy, and they sold to different countries large quantities of raw silk of which no account is made in these statistics. The American Consul at Lyons says that of the total amount handled, 8,000,000 pounds remained in Lyons and were worked into the finished article by the weavers there and in the suburbs of the city. In the matter of manufactured silk it is stated that all the old stock and an increased output were sold during the year. An increase of £1,340,000 in the value of the merchandise sold over the year 1905, and of £680,000 over 1904 is recorded. The activity in sales which commenced in the latter part of 1904 continued through the two succeeding years, the sales being most largely in light goods. The exports of silks from Lyons in 1906 amounted in value to £12,940,000 against £12,200,000 in 1905. The imports of silk for 1906 amounted to £1,600,000 and consisted largely of pongees, corah and tussah from the East, which are dyed and re-exported. The principal purchasers of Lyons silk last year were the United States, the United Kingdom, Germany, Switzerland, Belgium, Turkey, Italy and Austria. Five-sixths of the silk produced in Lyons are exported to England, the United States, and other countries beyond Seas, Continental Europe representing only about one-sixth of the consumers of the principal product of Lyons.

HOME INDUSTRIES.

The Price and Output of Copper. — The heavy fall in the price of copper, and the reasons for it, are matters of great moment to many home industries which have been seriously handicapped for some time past by the high price of the metal. Last week there was a further break of £8 15s. per ton in the price and the quotation finished at £65 10s. per ton, or £45 5s. below the highest of the year, and £18 2s. 6d. below the price in the corresponding week of 1906. Still, even now the mean price of the year is high if the average of the decade is taken, as is seen in the following figures: — Mean price in 1897, £49 6s. 10d.; in 1900, £74 7s. 6d.; in 1905, £72 10s.; in 1907, £82 2s. 6d. The average mean price of the ten years was £66 8s. 9d., or slightly in excess of the quotation at the time of writing. Of course, during the ten years the demand for copper has increased largely, but the output has increased in at least corresponding degree, and probabilities would seem to point to considerably lower quotations. It is noteworthy that the Quincy Mining Company, one of the oldest copper companies in the United States, and able to produce copper at the rate of 10½d. per pound, has felt it necessary to reduce dividends with copper at its present prices. The stocks of copper in hand in the United States are believed to be very large. Consumers would buy if business was active, but it is not. At a recent meeting of prominent American wire manufacturers it was generally agreed that business in recent months had fallen off to something like 50 per cent. Representatives of the brass manufacturers stated that their business had fallen off from 30 to 40 per cent., whilst the sheet copper business was practically at a standstill. It would seem to be much the same in the United Kingdom. Ten days ago Messrs. Lewis Lazarus reported that for the first time during the present fall there was evidence of concentrated selling by the trade, and the standard was pressed for sale wherever a willing taker was to be found. The position of the producer seems to be less strong than was generally supposed, private stocks being in greater quantity than has been generally assumed. The high price of copper has called a halt in certain lines of industry in which copper is usually in much demand, with the result that stocks have not been drawn upon so heavily as was anticipated, and manufacturers, counting upon still lower prices, will not buy at present rates. On the other hand, producers have to finance steadily growing stocks of copper, and that at a time of great monetary stringency. There would seem, therefore, to be grounds for the opinion that probabilities point to still lower quotations for copper before consumers can be induced, or forced, to buy in large quantities.

The Wool Trade.—Reference was recently made in these Notes to the way in which the Australian wool auctions are affecting those of London. Until recently the Australian auctions were of small im-

portance, the bulk of the sales being made in London, but during the last year or two the position has been reversed. During the wool year which ended on June 30, no less than 82 per cent. of the total clip of 1,663,000 bales was marketed in Australia, and it is expected that in the present season this proportion will be increased. On Wednesday next the London Colonial wool auctions begin, and it is expected that about 100,000 bales will be offered; and on Friday the Australian sales commence at Adelaide. More English buyers are said to have left than ever for the Antipodes, and large numbers have gone from the Continent and the United States. Some leading Bradford firms have sent out two, and even three representatives, the duties of a buyer attending the colonial markets being very arduous. Sales will follow each other in quick succession up to Christmas in Adelaide, Melbourne, Geelong, Sydney, and Brisbane, and afterwards there will be auctions at Launceston and Hobart, and the New Zealand markets will open. Meantime the top-makers at Bradford refuse to sell forward. Last year they sold heavily for future delivery. They reckoned upon the large increase in the Australian clip enabling them to secure wool cheaply, but their calculations miscarried. They were right in assuming a large increase in the clip (the actual increase was over 200,000 bales), but they did not reckon with the larger increase in consumption which neutralised the increased supply. Merinos and fine cross-breds not only maintained their ground, but increased in value. It remains to be seen whether the top-makers will better serve their interests this year by assuming the maintenance of present prices. There would seem to be a present probability of a full supply of raw material.

The Cotton Position.—There is more than the usual uncertainty as to the cotton supply. There has been drought in Texas, which, it is estimated, may reduce the yield from that State by a million bales. On the other hand, improvement is reported in other sections, and the planter is eager to sell at the present range of prices all the cotton which he can market during the early part of the season. The crop is undoubtedly late, which increases the danger from early frost, but against this risk is to be put the fear of a general reaction in business of which the decline in iron and copper is held to be an unmistakeable sign. Still, the market for cotton goods in the United States, as in the United Kingdom, shows no sign of serious shrinkage. The reports from Egypt and India as to the prospects of the cotton crop continue good, and if reliance may be placed upon a report just issued, written by the Japanese Resident-General at Seoul, on the cultivation of cotton in Korea, it would appear that that country's contribution to the world's cotton supply is likely to be substantially increased, and improved in quality. Meantime extensive shipments of yarn to the Continent continue. The imports of Germany in August were about double those of the same month last year, and Holland shows an increase of 50 per cent. During the last twelve months the exports from the United Kingdom were 224,810,000 lbs., as compared with 151,481,000 lbs. in the corresponding period of 1903-4. The annual holiday in the weaving mills of Lancashire, which has been longer than usual, is now over, and it is expected that the fine counts wages question will come up for discussion almost immediately. It is by no means certain that an arrangement will be arrived at. The operatives are believed to be in an uncompromising mood, which, if persisted in, may lead to a strike that with reasonable give and take might be avoided.

Shipbuilding and the Price of Coal. — At first sight it is not very apparent how the shipbuilder can be greatly affected by the present rise in the price of coal, great as it is, but in fact it is a very serious matter to him. If the shipbuilder is not a large consumer of coal either in the yard or the engine shop, he is amongst the largest consumers of iron and steel. The cost of finished iron and steel is seriously affected by the increased cost of coal. The chairman of the Steel Company of Scotland, Limited, has recently explained to the shareholders of that company how the prospects of the steel trade have been darkened by the rise in the price of fuel, and the cost of production of iron and steel is being increased at a time when reaction in America and Germany point to a lower range of prices. No industries will suffer more than the iron and steel from the rise in the price of coal, and dear iron and steel affect no trades more closely than those concerned with shipbuilding. If regard is had to output alone the shipbuilding record of the present year is highly satisfactory. In the seven months ended July 31 the output of the United Kingdom was 556 vessels of an aggregate of 943,016 gross tons. It is true that so far as tonnage goes these figures show some decline upon those of last year—943,016 tons as against 991,092 tons—but the vessels numbered 556 as against 461, and last year included the *Lusitania* and *Mauritania*, each of 32,000 tons, and quite exceptional in character. Apart from 1906 this year is much ahead of all records so far as output goes. If the August output is included, and the comparison is confined to the Clyde, that of the present year exceeds that of 1906, being 459,763 tons as against 449,772 tons, and excepting 1906 the output for the eight months greatly exceeds that of any other similar period on record. The new contracts of the eight months showed considerable contraction although for the month of August they were unusually good. September and October are generally active contract months but they will hardly be so this year with the rising market for coal and iron. Steelmakers must now ask higher prices for shipbuilding material than they were ready to sell at a short time ago. The peaceful settlement of the labour disputes which at one time threatened a serious crisis is a matter for

congratulation, but this year can hardly be a very profitable one on the whole for shipbuilders. The outlook for the men is better than it promised to be earlier in the year, for the new orders are sufficient to maintain active employment in many of the yards during the winter. But in order to keep the yards employed, shipbuilding and engineering employers have had to cut contract prices very low, encouraged thereto by the anticipation of a general decline in iron and steel material. They did not reckon with the rise of coal, due to the large export demand.

Wages in the Clothing Trade.—Statements made in a case in which a man was charged with begging have led to some misapprehension as to the rate of wages paid in the clothing trade. The accused alleged that he was a tailor's presser out of work, and had recently been engaged in finishing trousers at 1¾d. a pair. It seems poor pay, but the facts do not justify the newspaper heading, "Trouser-making at a Penny Three-farthings a Pair." There is a wide difference between trouser-making and finishing. Nowadays, no individual makes a pair of trousers, at any rate it is not the practice in the trade. What is known as "finishing" is neither a long nor a difficult job, and an average hand can, it is said, finish a pair in ten minutes. Assuming this to be correct, as experts say it is, the remuneration works out at something over tenpence an hour. The clothing trade attracts much unskilled labour, and women as well as men without any knowledge of tailoring enter the factories. When they are industrious and willing to learn they can earn a living wage, but many of them do not come under this category.

Hematite Iron. — The cessation of all demand from America, and the partial stoppage of Continental orders, have caused a great falling off in the demand for hematite iron, and North-West of England smelters have reduced their nominal figures to 80s. per ton net f.o.b. Warrant iron is at 76s. per ton, with indications of lower prices. The home demand remains good, but the shrinkage of the foreign demand necessitates some restriction of output, although orders in hand are expected to keep things active for another three months. Stocks at the end of last week stood at only a little over 10,000 tons, the lowest point touched for many years. The shipments of iron and steel during the last weeks show a heavy falling off, but the aggregate shipments of the year are largely in excess of the corresponding months of 1906.

GENERAL NOTES.

BANANAS IN FRANCE.—It is astonishing, says Mr. Consul-General Hearn (3283-152), in reporting on the trade of Havre, how popular bananas have become in France. Not so long ago the banana was a rarity; now it is to be found hanging up in every fruiterer's window. The bulk of the bananas consumed in Europe are imported from the Canary Islands by British firms. The West Indian banana does not appear to have reached the Continent in any great quantity as yet. In 1877 only 5,000 bunches of bananas were imported into France; this rose in 1901 to 50,000 bunches, and in 1904 to 250,000 bunches. Paris takes about half the quantity, and then the two chief consumers are Marseilles and Bordeaux. The wholesale price of a bunch is, on the average, 12s. 6d. The bananas are sold retail at three sous a piece, and as there are from 150 to 200 bananas on each bunch, that price brings the retail price of the bunch to from 16s. to 20s., which gives a profit of from 4s. to 8s. per bunch. The bananas sold in the South of France and Algeria, although sold under the name of Dahomey bananas, as a rule all come from the Canaries. The highest prices are obtained in the spring and autumn. Before France, encouraged by the high prices she has to pay for her bananas, takes to growing them herself in the many colonies suitable to their cultivation, it would be well, Mr. Hearn thinks, for British firms to stimulate the importation and taste for Jamaican and other West Indian bananas, which, in his opinion, are finer than the Canary fruit.

BELGIAN CEMENT.—In his report upon the trade and commerce of Belgium, just issued (Cd. 3727-1), Consul-General Sir Cecil Hertslet again directs attention to the systematic habits of the dealers in Belgian cement in passing off their productions of inferior quality as an article of British manufacture, or British origin, at exceptionally low prices, which cannot be approached by makers in the United Kingdom so long as they retain the high standard for which British cement is famous. Sir Cecil Hertslet says that the blame cannot be put so much upon the Belgian manufacturers themselves as upon the commission agents, and dealers of that class, who furnish any labels that may be required to the makers to attach to the barrels or casks when forwarded from the works, many of which labels are undoubtedly infringements of trade marks of makers in the United Kingdom. It seems to be difficult for the British manufacturer to trace the fraudulent imitations which are being passed off under his particular brand in the colonies and foreign countries. It would seem, however, that buyers are beginning to realise that much of the cement manufactured in Belgium, described as "Portland" cement, and having British names and brands, is not the genuine article, but is in every sense inferior to the British production, and in many cases is not entitled to be called "Portland" cement at all, according to the accepted standard. Of late there has been considerable reduction of Belgian exports of cement to the United Kingdom and British colonies.

Journal of the Society of Arts.

No. 2,862. VOL. LV.

FRIDAY, SEPTEMBER 27, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

EXAMINATIONS.

The programme for 1908 is now ready. The price of the Programme (containing the previous year's papers and the examiners' reports on the work done) is 3d. (post free 4d.) Copies can be had at this price on application to the Secretary, Society of Arts, Adelphi, W.C.

The examinations are now arranged under the following stages:—Stage I.—Elementary; Stage II.—Intermediate; Stage III.—Advanced.

The subjects include:—Book-keeping, Accounting and Banking, Shorthand, Typewriting, Economics, Précis-writing, Commercial Law, Commercial History and Geography, Arithmetic, Handwriting, and Modern Languages.

The Examinations will commence on Monday, April 6, 1908.

In the Advanced and Intermediate Stages First and Second-class Certificates will be granted in each subject.

In the Elementary Stage Certificates will be given in each of the subjects enumerated. These will be of one class only.

Certificates of proficiency will be granted in each grade to Candidates who pass in certain specified subjects during a given period.

In Rudiments of Music Higher and Elementary Certificates will be given; in Harmony Higher, Intermediate, and Elementary Certificates.

A fee of 2s. 6d. will be required by the Society from each Candidate in each subject in the Advanced and Intermediate Stages, and in the Elementary Stage a fee of 2s. for one subject, and 1s. for each additional subject taken up by the same candidate. The fees for Harmony and Rudiments nf Music are the same as for Stages II. and III.

Medals and Prizes are offered in each subject in Stages II. and III. Full particulars will be found in the programme.

Examinations are also held in the Practice of Music, and Vivâ Voce Examinations in French, German, Spanish, Portuguese, and Italian. For information as to these examinations reference should be made to the Programme.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

GOLD MINING AND GOLD PRODUCTION.

By Prof. John Walter Gregory, D.Sc., F.R.S., F.G.S.

Lecture III.—Delivered February 11, 1907.

III.—Gold Extraction, the Variations of Mines in Depth, and the Gold-mining Industry.

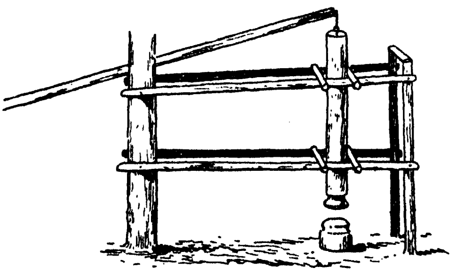
The fame of Rudolph Eric Raspe as the author of "The Surprising Adventures of Baron Munchausen" has eclipsed his former infamy as a mining adventurer. During his varied career Raspe found himself in Scotland, where he raised £30,000, with which to exploit some vast mines of mercury that he claimed to have discovered in the north-western Highlands. To promote his scheme and increase his own authority on the matter, he published in 1791 an English translation of Baron Inigo Born's valuable work, "The New Process of Amalgamation of Gold and Silver Ores;" for Raspe maintained this process would lead to an immense demand for mercury, as with it, gold could be obtained from rocks which had hitherto yielded none. Any Scotch mercury mines that there may be, are however still unworked; for Raspe and the £30,000 passed silently away to other fields of activity.

The use of mercury for collecting alluvial gold is very ancient, as it is mentioned by Pliny; but it was apparently not until 1566, that it was found that the process of amalgamation would extract gold and silver from other ores. This discovery, made in Mexico by a Spaniard, Fernandez de Velasco, opened a new epoch in the history of gold-mining; for it supplied an economical method of extracting gold from ores, whence it could not be recovered by washing.

The Stamp Battery.

The ancient method of working gold-quartz ores was to break the quartz into coarse fragments and then grind it to powder between a hard stone and a flat surface of rock, like an ancient corn mill. The underlying rock is worn away, forming a groove, in which the broken quartz can be mixed with water and thus washed while it is being ground. Such simple hand quartz mills may be seen beside some of the old mines in Rhodesia, and the grinding stones, balls of a tough diorite, are found beside them. This simple hand mill is the most primitive form of quartz crushing machine. The second device was probably some kind of pestle and mortar, which, in the form of the hand dolly, a strong iron pestle and mortar, is still used in prospecting and sampling. The passage thence was easy to a pestle work by a lever, such as is still used by the Chinese in the Northern Territory of South Australia.

Fig. 19.



A Primitive Stamp. Still used by the Chinese Miners in the Northern Territory of South Australia. (After Basedow.)

Gradual increase in the size and complexity of the mechanism led in time to the German mill, which was developed in Germany at the beginning of the sixteenth century in order to crush the ores of the Erzgebirge and the Harz Mountains. It is illustrated in the excellent figures in Agricola's "De Re Metallica," published at Basle in 1556. The German battery may still be seen and heard in this country in the Cornish tin mines. It consists of a broad flat-footed pestle, called a shoe; the pestle is lifted by a projection on a revolving shaft, and falls by its own weight upon fragments of ore. At first the ore was pounded upon an open floor and was crushed dry, but the advantages of enclosing it in a box and washing it at the same time were obvious, and Agricola's book shows also an improved battery provided with a mortar-box. These batteries were worked by men or horses, but generally by water power. The German battery remained the best thing in quartz-crushing machinery until it was taken in hand by the miners of California, who improved it into the modern stamp battery. The Californian battery differs from the German by having circular pestles or stamps, which are rotated while being raised so that the striking face of the stamp is worn evenly. The stamps are lifted by cams fixed on a revolving shaft, they fall on to dies in the mortar-box, and the ore is smashed between the stamps and the dies. (Fig. 20, p. 1039).

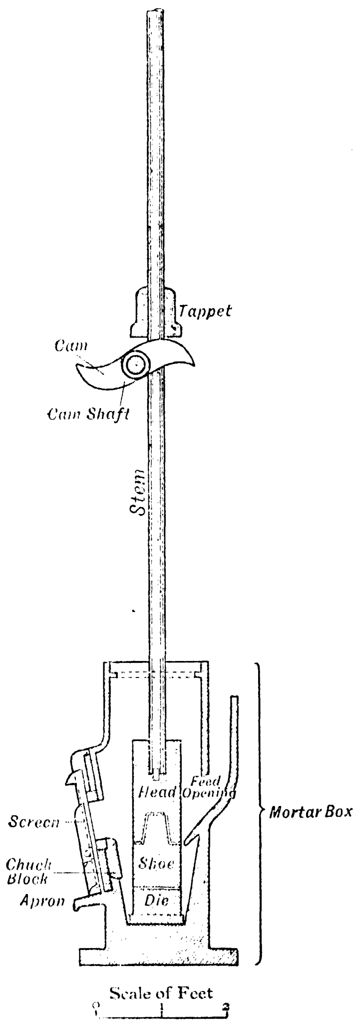
The stamps are usually grouped in sets of five, each set in one mortar-box; the sets are arranged in series, each of which, in large mills, usually includes fifty stamps. The greatest number in any one mine is at the Homestake in South Dakota, which has a mill of 1,000 stamps, and even larger mills are proposed on the Rand.

The ore may be fed into the mortar by hand or automatically; the finely crushed ore or "pulp" is splashed about in the mortar-box, where it comes in contact with the mercury usually kept there. This mercury catches some of the gold, and more is caught on the "chuck block" in front of the screen, through which the pulp escapes from the mortar. This "inside amalgamation" is, however, not always used. How much of the gold it is wise to collect in the mortar-box depends on many factors which are not all mechanical. One important consideration may be the theft of amalgam if left exposed on the plates. On the Rand this loss has been described as a severe tax on the mining industry. At Mysore it is found advisable to crush the ore extremely fine, in order to collect most of the gold inside the mortar-box, where it is less exposed to thieves.

All branches of mill management have been discussed in great detail. The best order in which the stamps should fall, for example, has quite a literature of its own: and there is no

doubt the efficiency of the battery can be greatly increased by a suitable order of the fall of its stamps. There has also been prolonged discussion and experiment as to the best arrangement of the screens. They are used of different heights, and there has been much controversy as to whether it is

FIG. 20.



CROSS SECTION (Scale ½ inch to 1 foot) THROUGH A STAMP AND MORTAR-BOX.

better to have the screens vertical, as is usual in Australia, or to have the upper side inclined outward, the usual American practice, which is adopted also in Mysore and South Africa.

There are many types of stamp battery, which differ in very important respects. During recent years the stamps have been increased in weight from four hundredweight to 1,500 lbs. At the same time, the number of blows struck per minute has been increased by reducing the fall of the stamps to from six to nine inches, and it is thus possible to give them a more rapid action, each stamp falling perhaps one hundred times a minute. The desire for still greater speed has led to more fundamental changes.

The more blows a stamp gives, the more ore it will crush in proportion to its weight; hence it is desirable for a small mine, to which transport is very costly, to drive its battery as quickly as possible. Accordingly the efficiency of the stamps has been increased by batteries in which the blow of the stamps is not due to gravity alone. In mills of the Tremain type, which have been used with success in Rhodesia and West Africa, the stamp is both lifted and driven down by steam; and thus a light two-stamp mill will do more work than a heavy five-stamp gravity battery.

A quicker action can also be obtained, as in the Morison battery used at the Meyer and Charlton Mine, Johannesburg, by working the stamps by cranks, whereby 1,600 lbs. heads are driven at the rate of 130 blows a minute, and crush quartz at the rate of ten tons a day.

A second line of reform raises the crushing power of the battery by increasing the rate of discharge from the mortar; this can be done by enlarging the area of the screens through which the pulp escapes. One method is to have screens on both the front and back of the mortar-box; but this reform has not found general favour, though it has been used at many Australian mines with good results. The extreme development reached on this line is the Merrall Mill. (Fig. 21.) In that machine each stamp works in a separate mortar-box, which has a screen on each of its four sides; hence the discharge is naturally much quicker than when the material is discharged only through one front screen.

Another and still more revolutionary change in ore crushing is following from the need for the very fine crushing usually necessary for cyanidation. This reform may, therefore, be considered after reference to the methods of gold extraction from the crushed ore.

GOLD EXTRACTION.

The processes of gold extraction may be divided into four main groups—amalgamation, smelting, chlorination, and cyanidation.

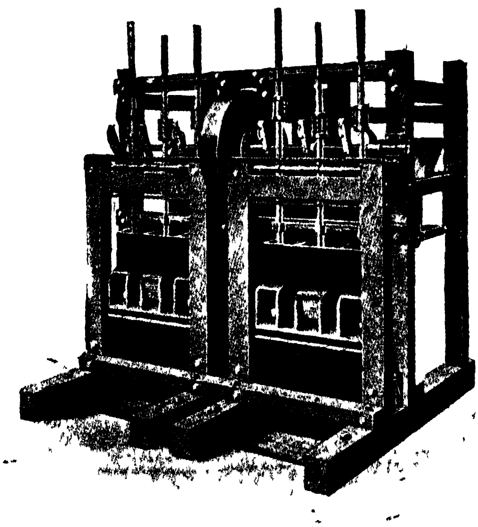
Amalgamation depends on the power of mercury to combine with gold to form an amalgam. The process is applicable to ores

carrying free gold, even though it may be completely enclosed in pyrites; as it then usually occurs free in cracks or cleavage planes in the pyrites, and thus can be recovered, if the ore be ground sufficiently fine for the mercury to come in contact with the gold.

Amalgamation may be begun in the mortar-box; the rest takes place on sloping copper plates, rubbed with mercury, which are situated in front of the battery.

Battery amalgamation cannot recover all the gold. The gold contained in fragments of pyrites, "amorphous" gold, gold that has been over hammered, and any covered with oil or slime, all escape amalgamation. Such

FIG. 21.



MERRALL STAMP BATTERY.*

gold and gold-bearing material has to be collected by some process of concentration into "concentrates." They may be obtained by washing the pulp from the battery down a long channel, and collecting the heavier material by riffles, or on the rough surface of strips of canvas or blankets on the floor of the channel; or the material may be sorted according to the specific gravity of the particles on revolving tables known as buddles; or on shaking tables (vanners and the Wilfley); or by "sizing" the materials by currents of water through such appliances as pointed boxes (Spitzkasten).

The concentrates thus obtained may be ground in Californian mills or Berdan pans, and then amalgamated. Some concentrates, however, do not yield their gold by amalgamation, and require more complex chemical treatment. The oldest method was smelting, and this may still be advisable for some refractory sulphides and tellurides, such as some of the ores at Cripple Creek and Kalgoorlie. Economic smelting requires a mixture of different types of ores, which are not usually found in the same mine or mining field; so it is conducted in special smelting centres, such as Denver—which collects the various ores of Colorado—and Swansea and Freiberg, in Saxony, which smelt ores received from world scattered mining fields.

Smelting is of less importance in dealing with gold ores than the chemical processes of chlorination and cyanidation.

The chlorination process is due to the work of Percy, in 1846, and of Plattner, in 1848. It is an application of the power of the gas chlorine to combine with gold forming auric chloride which is soluble, and can thus be leached out of the altered ores. The formula representing the process is:—

$$3\,Cl + Au = Au\,Cl_3.$$

The gold can be precipitated from the auric chloride solution by charcoal, iron, ferrous sulphate, &c. The process is applicable to many complex ores, and is used, for example, at Cripple Creek, and in dealing with pyritic concentrates in many fields; but it has been superseded to a great extent by the younger and simpler process of cyanidation, which has the advantage of not requiring the roasting of the ore.

The Cyanide Process.—The cyanide process is due to MacArthur of Glasgow. It depends on the fact that a weak solution of cyanide of potassium will disolve gold in the presence of oxygen as auro-cyanate of potassium.

$$Au_2 + 4\,K\,Cy + O + H_2O = 2\,K\,Au\,Cy_2 + 2\,K\,HO.$$

The gold can be recovered from the solution by precipitation with zinc or electrically by the Siemens-Halske process. There are many variations in cyanide practice in accordance with the varying nature of the ores. Some American mines and the Great Boulder Proprietary Mine at Kalgoorlie use sodium cyanide instead of potassium cyanide. Bromocyanide is added to the vats as well as potassium cyanide in treating the telluride ores of Cripple Creek and some of the mines of Kalgoorlie (the

* This block is kindly lent by the Sturtevant Engineering Company.

Lake View Consols, Oroya Brownhill, and Kalgurli mines).

The cyanide process is very simple and economical. It is generally used after the coarse gold has been separated by amalgamation. The crushed material that is carried over the copper plates of the battery is called the tailings. If the mine is in a hilly country, the natural slope of the ground is used so that the tailings can be carried through the various tanks by gravity; but in a level country, such as the Rand, the tailings are lifted from the battery by a high tailings-wheel to a platform, which gives sufficient fall for a current of water to carry the material through the remaining stages of the separation.

The tailings consist of sand and of fine material of the consistency of mud, which is called slime.* The sand and slime are separated by two sets of separators, the "spitzlutten," and the pointed boxes or "spitzkasten"; from them the light slimes are carried off at the top and the heavy sands from the bottom. The heavy materials collected by the first separators are known as the "concentrates"; and they may be ground up and the gold extracted by mercury, or they may be treated by the chlorination process.

The rest of the sand passes into huge tanks, wherein it is allowed to soak for some days in a weak solution (usually ·1 per cent.) of cyanide; or it is stirred up with the cyanide in tanks by agitators. The gold is dissolved and the solution drawn off from the bottom of the tanks and passed to the extractor house.

The slimes are mixed with lime, which coagulates them, so that they settle while most of the water runs off clear. The settled slimes are then stirred up with cyanide, their gold is dissolved, and this solution also passes on to the extractor house. There the various cyanide solutions are run into extractor boxes, and the gold precipitated. Zinc is the usual precipitant, and the gold is collected from the precipitate by smelting in a furnace with a flux, such as one of borax, sand, and bicarbonate of soda, or of borax, sand, and manganese dioxide. An electric method of precipitation is sometimes used instead. The barren slimes from the cyanide tanks are allowed to run away if there be a natural fall, or they may, as at Kalgoorlie, be stacked by a tailings elevator, and ultimately used to fill up the excavations in the mine.

* Its particles are of a diameter of not more than ·002 inch in diameter.

FINE CRUSHING—THE TUBE MILL AND FILTER PRESS.

This invaluable cyanide process was at first used to supplement the other processes, but it has to a large extent supplanted them, and threatens to do so still more in the future. It had one difficulty from which at first there seemed no escape. Dilute cyanide is only an effective solvent for porous or very finely crushed ores; it therefore requires the fine crushing of the material subjected to it. But ore ground so finely that all its gold can be recovered by cyanide is as impermeable as mud. The resistance to the entrance of the solution can be overcome by stirring the slime and solution together in agitating tanks. But when the fluid has got in, the mud takes such a firm hold of it that the gold solution will not drain out. Out of this dilemma Australian mining led the way.

The first process was to improve the system of crushing the ore. The stamp battery is not a suitable instrument for the breaking up of big blocks of stone, for they are apt to tear and smash the screen. Again, the battery is not economical in very fine crushing; for, unless the supply of water, the power, and the size of screen be perfectly adjusted, the stamps waste their power in pounding fragments of quartz in a yielding mass of soft sand.

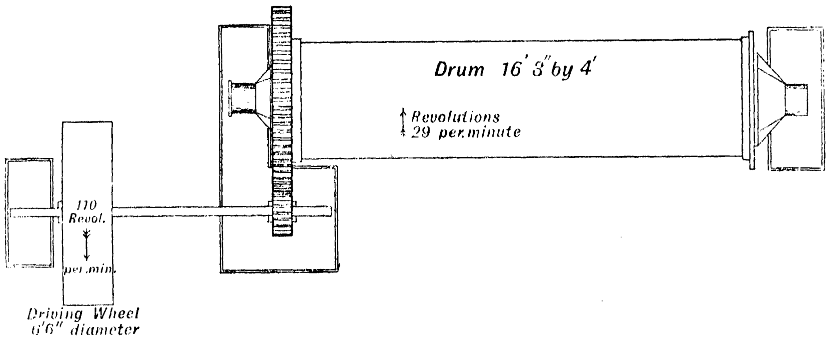
Accordingly, the battery wanted help on each side of it, so that it may be confined to the work for which it is most effective. The ore is therefore broken into fragments of suitable size by rock breakers. The ordinary type of crusher used for breaking rocks into road metal are employed for this purpose; the ore may be crushed between powerful jaws, or by a gyrating steel cone inside a massive steel funnel. The material can be passed through series of rock breakers, each breaking to a smaller size; and instead of this tandem arrangement there may be a compound crusher, such as that of the Sturtevant Engineering Company. The ore is thus reduced to the size most suitable for the battery to deal with it.

The use of rock breakers has long been adopted in many mining fields; but the relief of the stamp battery by the use of special fine grinding appliances has been more recent, and has been productive of more important consequences. The first step was to relieve the battery of the finer crushing. The mesh of the battery screens was enlarged so that the ore escapes as sand instead of as slime, and each stamp therefore crushes much more

ore than it would otherwise do. The Waihi Mine, for example, increased the output of its batteries 30 per cent. by enlarging the mesh of the screens from 40 holes to the linear inch to only 20 holes. And according to Chester's experiments, when the Rand ore is crushed through a 10-mesh screen, each stamp will crush 9¼ tons a day; whereas the same battery with a 30-mesh screen crushes only 4·64 tons a day. The stamps of the miner, like the mills of the Lord, grind slowly when they grind exceedingly small.

The material that escapes from the mortar-box through these coarser screens passes over amalgamation plates which collects the larger particles of gold. The sands had then to be reduced into slime by some instrument better adapted for fine grinding than the battery.

FIG. 22.



PLAN OF A TUBE MILL as used at the Lake View Consols Mine, Kalgoorlie.

Various forms of accessory grinding machines have been employed, such as the Huntingdon mill, the grinding-pan, and the ball mill, but the most famous now is the tube-mill. This machine was developed in cement works to grind up soft limestones. The limestone is fed into a revolving cylinder, and churned up with hard flint pebbles which act as millstones, and grind the limestone to slime.

This machine, variously known as the tube-mill, the flint-mill, or the grit-mill, was introduced into gold mining at Kalgoorlie where it was well suited to the soft tough ores of that goldfield.

A diagram of the larger tube-mills used at the Lake View Consols Mine is given in Fig. 22. It consists of a revolving drum, 16¼ feet long by 4 feet in diameter; it is lined with manganese steel plates one inch thick; they are used until they are worn down to a quarter or an eighth of an inch in thickness. The drum is half filled with a load of rounded flints weighing about 4½ tons; some 35 tons of sands are run into it. The mill is rotated at the rate of 29 revolutions per minute, and the flints grind the sand into fine slime. The mill is mounted on two hollow trunnions through which the ground material is carried away by a stream of water. The fine slime flows to the separating tanks, and the coarser material is returned to the mill. About 300 tons of ground ore pass through the mill in a day, and some of the material goes through it eight or ten times before being reduced to slime. The flints are gradually worn away. The tube-mill, illustrated by Fig. 22, consumes 1,000 lbs. of them a month. The flints may remain in mills where they are completely destroyed; but it is sometimes the practice, as at the Oroya-Brownhill Mine, to sift them periodically, and reject all those that will go through apertures of 1½ inches diameter, as they are found to contribute little to the grinding, while they use up power.

The slime from the tube-mill flows into tanks, where it is stirred up with cyanide solution by revolving agitators; the finest gold is therefore dissolved; but no process of natural draining will extract all the solution from the slime.

Recourse is therefore had to Dehne's filter-press. The slimes may be roughly drained, and placed in layers between sheets of cloth in a press, or they may be pumped into it by a plunger pump. Weak cyanide solution is forced through the press to dissolve any remaining gold, and then the solution is washed out of the slime by a current of fresh water driven through the press by a force pump.

This combination of fine grinding and the filter press has given increased scope to the cyanide process, for it renders possible the

almost complete extraction of the gold from slimes. South Africa has recently adopted tube mills with characteristic enthusiasm, and thereby gained increased profits by extracting gold which would otherwise have gone to waste. But meanwhile in Australia their use has been reduced on the ground that they are extravagant of power. They have been discarded at the Ivanhoe Mine for example, and grinding pans used in their stead. It is held by many Australian miners, and by Messrs. G. A. and H. S. Denny from their South African experience, that grinding pans do the same work as a tube-mill, and more cheaply. According to the results of one set of experiments, 30 horse-power applied to a grinding pan does as much work as 70 horse-power in a tube-mill. The Australian experiments have been severely criticised, but the miners who first realised the value of the tube-mill may probably be trusted to treat it fairly in their tests.

The policy for which the tube-mill was introduced is unquestionably sound, and will be continued; but it is possible that the tube-mill itself has not come to stay, and may be replaced by some more economical machine. The filter press also is being attacked in Kalgoorlie, and the Ridgway Atmospheric Slimes Filter is claimed to do its work as efficiently, while it is more convenient, as it acts continuously and automatically.

Suggested Abolition of the Battery.—The great development of cyanidation rendered possible by these reforms is threatening the abolition of amalgamation and even of the stamp battery. In some places the battery has been abandoned in order to save water. The battery is a very thirsty instrument; it uses on the Rand, according to Mr. G. A. Denny's estimate, ten tons of water to crush one ton of ore. The system of dry crushing reduces the consumption of water, and avoids the use of amalgamation. The ore is ground between rollers or in pans, and then passed at once to the cyanide tanks. This system was once employed at Waihi, in New Zealand, and may be seen in use at the Wanderer Mine in Rhodesia, where the broken oxidised ore is readily permeable, and the gold is extracted at a total cost for mining and milling of 6s. 9d. per ton.

The most advanced attack on the battery is that proposed by Messrs. G. A. and H. S. Denny, and to some extent adopted in the very original plant erected by them at the New Goch Mine, Johannesburg. The battery is fed with cyanide solution instead of water, and the ore is kept circulating in cyanide throughout its course through the separating plant. The gold is all dissolved during this circulation, and there is no need for huge cyanide tanks and special agitators. In the New Goch Mill the ore is broken to fragments in rock breakers, then crushed to sand in a stamp battery; next it was ground to slime in tube-mills, which have, however, been replaced by grinding pans. The gold solution is extracted from the slimes by filter presses.

The logical development of this system, with its restriction of the work of the battery by rock-breakers on one side and all-sliming by fine grinders on the other, and the abandonment of amalgamation, is the abolition of the battery altogether. And this revolutionary proposal the Denny Bros. have already advocated. They recommend the crushing of the ore in a series of rock breakers; the reduction of all of it to slime in grinding pans; its continuous treatment by cyanide as it passes through these machines and from one to the other; and the treatment of the slime in filter presses.

Threatened institutions however live long; and it may be long before the resounding roar of the stamp battery ceases upon the goldfields, although that machine has already lost the monopoly of ore crushing which it so long enjoyed.

Gold Yield of 1906.

The gold supply of the world is now unprecedented; and is apparently still growing. The total yield for 1906 is estimated at over £80,000,000 which is the highest on record, and twice as great as in 1896, and four times as great as in 1886, or only twenty years ago.

This great yield has been contributed by 46 countries, of which the three chief producers are the Transvaal with a yield of £24,579,987, the United States with a yield of £19,431,040, and Australia with a yield of £16,570,312. The Australian output, to which the State of Victoria has been contributing for 56 years, shows the baselessness of the old fear that gold mines are all necessarily shallow. Some ore shoots are certainly limited in depth; but others go down deeper than it will probably pay to follow them for years to come.

Variations of Mines in Depth.

The future of any goldfield depends on the depth to which its ores will continue; opposite opinions have been freely expressed as to the depth to which gold ores may extend. Both

views are locally correct. There may be two adjacent mines, in one of which the ore shoots may be shallow, in the other they may continue downward for thousands of feet. This difference is not a capricious accident, but is the result of definite ascertainable causes.

The once prevalent belief in the shallowness of gold deposits was largely the result of the unquestionable fact that, as a rule, gold veins become poorer and less profitable to work as they are followed deeper. The outcrop of a lode is the easiest and cheapest part of it to work for many reasons. The ore is decomposed and soft, and contains many cavities, so that it is easily mined; a block of it weighs less than an equal sized block of deeper ore; the gold is usually visible to the naked eye, and is very conspicuous in the rust-red ore. In the deeper levels, on the other hand, the ore is compact, hard, and heavy; the gold may be combined with the pyrites and so invisible and perhaps difficult of extraction; and below water level the working places have to be drained by pumping.

Hence the miner finds the deeper ore more troublesome and less profitable, and it has to be worked on a much larger scale than is possible to a party of working miners. The surface ore, moreover, is both absolutely and relatively richer, owing to the processes of surface and secondary enrichment. Surface enrichment is due to the rapid precipitation of gold from a gold-bearing solution when it approaches near the surface of the earth; for its temperature is then quickly reduced, and the oxygen and carbonic acid in the surface waters precipitate all the gold that has escaped deposition in deeper levels.

Secondary Enrichment. — This surface enrichment is aided by secondary enrichment. This process may be illustrated by reference to a quartz vein, in which gold is uniformly distributed. If the surface of the mining field be lowered by denudation, the gold in the top of the lode is dissolved by a solution formed by the action of the rain-water on the iron pyrites in the lode. The gold is carried a stage lower, where the iron sulphate is reduced and the gold and pyrites re-deposited. Hence the new top of the lode contains the metals originally distributed through twice the length. This concentration is repeated again and again, until a rich gold patch, such as the famous Londonderry pocket, may cap a comparatively worthless lode.

The richness of the gold quartz lodes at their outcrop led to the view that gold ores are always shallow, a doctrine which received most authoritative expression from Murchison; and at one period in the history of gold-mining the incoming of the sulphides meant the abandonment of the mine.

Mining Costs.

The deeper refractory ores can, however, now be treated, and the downward limit of mining is determined sometimes by the ending of the ore-shoot, and sometimes by the grade becoming too low to pay the increasing costs of mining. There is no simple universal rule which governs the depth of gold ores. The downward extension of each field must be judged independently, considering its geological structure, and the quantity of its ores.

In many fields the gold ores continue deeper than it is at present possible to follow them profitably. But the range of mining is being steadily enlarged, for though the difficulties increase as mines deepen, the costs may be reduced by working on a larger scale, and with improved machinery. The winding by hand or whim is replaced by a powerful engine; the shaft is enlarged, and instead of being kept vertical, may be inclined so as to keep close to the lode, and thus avoid the cost of long cross cuts through barren rock, and unnecessary underground haulage of the ore. Inclined shafts are used all along the Rand, whereas most American and Australian shafts, like the lodes they work, are vertical. Modern shafts and cheap haulage; machine drills, which in large operations are probably always more economical than hand labour; and the more perfect adjustment in processes of gold extraction have all contributed to the steady reduction of mining costs. The consideration of costs in different fields involves so many uncertain factors that it is not always easy to make fair comparisons. Thus in Victoria, for example, fields with the same conditions of wages and transport, and mining ore of the same hardness from similar country rocks, have costs varying from 33s. 11d. per ton of 2,240 lbs., at the North Woah Hawp Mine, which is doing mainly pocket mining, to 20s. 6d. at the South New Moon at Bendigo; one mine on the Bendigo Goldfield, the Central Ellesmere, from 9,480 tons, yielding 1 1/4th dwt., or 4s. 10d. per ton, did not quite pay its expenses, though a neighbouring mine secured a profit out of a yield of 5s. 4d. per ton.

The range of mining costs may be illustrated by the following examples. In Mysore, the

costs at the Mysore Mine are 32s. 1d. per ton of 2,240 lbs.; on the Rand, the average for 1904 was 30s. 8d. per ton of 2,000 lbs.; in Mexico, the costs of the El Oro Mine are 28s. 3d. per ton of 2,000 lbs.; Western Australia, in spite of its refractory ore and costly water, has costs of 18s. 5d. per ton of 2,000 lbs. at the Ivanhoe Mine, and 16s. at the Great Fingall.

Rhodesia, though hampered by long railways and its costly pioneer development, has creditably low costs; the average of six typical mines is 23s. 11d. per ton of 2,000 lbs., while individual large scale open-cut mines work more cheaply; the costs at the Wanderer Mine, for example, being about 6s. 9d. per ton of 2,000 lbs.

The United States shows such low costs as 10s. 3d. per short ton from the Homestake Mine of South Dakota, and in some of the gold-quartz lodes of California; the cheapest great American mine, the Alaska Treadwell, which crushes partly by the aid of water-power for 6d. a ton, has total costs of 5s. 8d. per ton of 2,000 lbs.

Still more remarkable is the record of the Stewarts United Mine in the Bendigo Goldfield where, according to the official returns of the Victorian Mines Department, a gold-quartz lode was mined, in 1905, at a profit, although the ore, of which 7,104 tons was raised in the year, yielded only 1⅓ dwt., or 5s. 4d. of gold per long ton.

Every mine manager is, or should be, engaged in a never ending struggle with costs. He may win by inventing new processes of ore treatment, or by greater economy in management. But when all has been done in these directions it may still happen that the ore is too low in grade for profitable working. Most men who have visited mining fields must have been grieved by the pathetic position of a mining engineer striving against difficulties which rendered financial success at the time impossible. The only chance in many such cases is in the reduction of the cost of living and of wages, by changes in the general condition of the district. There may, for instance, be two mines containing ore of the same value and bulk: one may be a valuable property; in the other the ore may be worth the price of road metal; for the one mine may be in a locality with good roads and a settled agricultural population, so that transport and food are cheap, and the conditions of life so comfortable that miners will accept comparatively low wages. The other mine may be in uninhabited back country, with costly transport and no local food supply; hence wages must be high to satisfy the cost of living and compensate the miner for the risks of taking employment remote from other fields of industry. In such cases the wisest policy may be to delay the development of the mine until the economic conditions can be altered and there is a chance of working it with success. Its premature development involves the tearing out of the rich ore patches with a precarious chance of profit, and the low grade material must be left unworked, and is, perhaps, wasted for ever.

Gold Mining as an Industry.

The credit of gold mining suffers from a reputation for reckless speculation, but the common view of its unprofitableness is exaggerated. It is sometimes said that the gold in the world costs more to produce than it is worth. In some young fields this statement is true, but it is ridiculous when applied to a State like Victoria, which has yielded £280,000,000 of gold in 56 years. It has been claimed, on the evidence of a census of the failures of gold mining companies, and of those engaged in ordinary industrial and agricultural work, that gold mining has lost a smaller proportion of the money subscribed for it than other industries. This result is intelligible, for gold mining is the one enterprise which has nothing to fear from the state of the market. The product is indestructible; its cost of transport is inappreciable; and there is no fear of a slump in price by over-production. The three great causes of failure in gold mining, are (1) over capitalisation; (2) rule of thumb procedure, leading to the choice of unsuitable methods; and (3) the frequent necessity for distant and therefore often expensive control.

The most sensational failures have been reckless extravagance due to over haste in the development of a field in consequence of a sudden boom. The history of Coolgardie with its wild waste of British capital in hopeless schemes is an example of this type of failure. Of the three causes of failure, the greatest is over-capitalisation, due to extravagant hopes, which are generally based on false analogies. This loss would be lessened if investors would estimate the value of a mining property for themselves, and trust for reward to dividends from the mine and not to profits from the share market. The estimation of the value of a mine involves three factors :—

1. A true appreciation of its geological structure, so that its future may be estimated by the history of a really similar mine.

2. An estimate of its probable life is often speculative, but may be a matter of simple calculation. It is usually necessary to consider separately ore already proved to exist, and that of which the existence is problematical, but which may be reasonably expected to occur, and to be workable at a profit.

3. The cost of extraction, dependent on local economic conditions, the quantity of the ore available, and the readiness with which the gold can be extracted from it.

Gold mining may be organised on two very different systems. It may be developed as a local industry, or as an investment for distant capital. The method which has found most favour in Eastern Australia, for example, is that of local development. A mine is discovered by a prospector, who works it himself or with a party of "mates" until they have exhausted the outcrop, and the depth becomes too great for their simple appliances. Their work, however, has shown the value of the upper part of the lode, and probably determined the position and length of the ore shoot.

A few thousand pounds are raised by local investors and spent in the erection of a small battery and the construction of a shaft. This money, judiciously and economically spent, probably raises sufficient gold to pay for a larger equipment and more extensive development. Thus the mine is made to develop itself. The Mount Morgan Mine, for example, produced its vast output without, according to a recent speech by Sir Horace Tozer, any capital at all; and the Madame Berry Mine won its million and a half of gold with a capital of £15,000. The great advantage of this method is that no great sum of money is risked, while the future of the mine is uncertain; and there is no insatiable drain upon the profits of the mine to pay the interest on a huge capital. The drawbacks are that such mines are often begun by men of limited experience, who may be baffled when they meet new conditions; and if the mine strikes a zone of barren ground, it has no reserve fund with which to prospect for better ore, and has to make calls upon the shareholders. There is no strong economic objection to the system of calls, which merely assumes that shareholders are capable of investing their capital more judiciously themselves than a mining company can do it for them. It often happens, however, that such calls give a mine a bad name. The shareholders are discouraged, they refuse to subscribe, and the mine may be abandoned, when further prospecting would have given it a new lease of life.

The antithesis of this method of gold mining is that which has been found necessary in South Africa. The prospector finds some indications of a mine, pegs out a claim, and sells it to a syndicate. The syndicate founds a Developing Company to develop the mine. The Developing Company may build a branch railway to the locality, erect the necessary plant, sink shafts, drive levels, and prove the mine by elaborate and costly sampling. Years later, the Developing Company founds a Mining Company to mine the property thus opened up. All this time the capital has been growing steadily, and the mine starts work with a handicap, which, though a good property, it cannot bear. There are mines in South Africa, with only a five or ten stamp mill, which have to pay the interest on a capital of £100,000 or £200,000 before they begin to make a profit, and repay the money that has been spent on them. A ten stamp battery, unless supplemented by other grinding appliances, cannot be expected to crush more than 15,000 tons a year. If the mine have a capital of £150,000, it has an interest charge, at 5 per cent., of £7,500 a year, and must earn a profit of 10s. per ton of ore crushed to pay the interest alone. Only the profit earned in excess of this very creditable amount is available to refund the capital.

Both systems of mining have their critics and advocates. The East Australian method is especially condemned for the comparatively crude sampling which is possible with it. But both methods have their uses, and are right if applied where they suit the local opportunities. The present great output of gold is due to the adaptation of mining methods to the different needs of widely-scattered fields; and the industry as a whole is well-managed, in spite of the gambling in shares, which is parasitic on it. Its success is indispensable to modern industrial prosperity, and it has had a deep influence on economic theories. Thus, in Bryan's opening speech in the present electoral campaign in the United States, he explained that he had abandoned bimetallism, as that system was no longer advisable, owing to the unexpected increase in the world's gold supply. The great existing gold output may be regarded with the more satisfaction, as the success of one country is not gained at the expense of the rest. There is no underselling, and the pro-

gress of one mining field usually adds to the prosperity of others. All the chief mining countries have contributed to the methods of modern gold mining. Germany invented the stamp battery, which owes its present high efficiency to America. Percy, of London, gave us chlorination, and J. S. MacArthur, of Glasgow, the cyanide process. California devised hydraulic sluicing, and New Zealand the gold dredge; while Australia, besides leading the way in deep gold-quartz mining, developed the modern system of fine-crushing and filter-pressing. Every important advance helps gold miners throughout the world, for, to the honour of the industry, there is no attempt to keep gold mining processes as jealous secrets. Gold miners of all nations recognise that they are colleagues and not competitors, and share their successes together as an international, industrial brotherhood.

DIAMOND CUTTING IN AMSTERDAM.

Among the many industries of Amsterdam that of diamond cutting has long been an important one. Since the fifteenth century it has been extensively carried on, and at the present time no fewer than sixty firms are registered in Amsterdam as diamond cutting or diamond polishing companies. Some of the firms restrict themselves entirely to one process, that of diamond polishing, while others carry out the whole of the three processes — diamond splitting, diamond cutting, and diamond polishing. According to the American Consul at Amsterdam, in one of these typical complete factories 90 per cent. of all the many thousands of rough uncut diamonds received every year come from South Africa and those principally from Kimberley. It gives some idea of the importance of this industry in Amsterdam to realize that 400,000 diamonds were cut and polished in this factory in one year alone, and that 300 to 500 men are daily employed in the different workshops by this one company, which also employs about twenty women, who are entrusted with the very important work of diamond cutting. Although the firm was established in 1843, it was not until 1875 that women were employed in the factory, but so satisfactory was the experiment that now nearly the entire work of diamond cutting is done by them, thousands of diamonds passing annually through their hands.

The first of the three processes through which the rough, uncut diamond has to pass is that of splitting the stone. About twelve men are employed in this task, which is all done by hand without the aid of machinery. It is not a lengthy process unless the stone contains a great many flaws, for an ordinary diamond weighing about 10 carats can generally be split in fifteen minutes. The object is to divide the rough, uncut diamond (containing flaws) into several pure, flawless stones, and in order to do this strong pressure is exerted on the weak spots (caused by flaws) by means of a diamond-tipped tool, which is held in the right hand. It is an old and well recognised principle that "nothing but a diamond will cut a diamond." In the left hand is held a curiously shaped little frame into which the rough diamond now to be split has been firmly fixed. Great pressure is then used on the weak spot, and in a few moments the diamond splits into two portions. Should there be any more flaws in either of these sections the process is repeated until several pure flawless diamonds lie on the rough wooden tables of the workmen, ready now for the second process, that of cutting. This process, like the first, is almost entirely performed by hand in the factory referred to, but with one striking difference—the work is done by women and girls instead of men. Only in the case of very hard difficult stones is machinery necessary, and then men are employed to use it. The work of diamond cutting is a delicate and difficult task, very trying to the eyes too, for some of the diamonds are so minute that 400 of them or more may weigh only half a carat. Each worker is responsible for the packet of diamonds she receives at intervals from the forewoman, and if by accident she loses one of the precious stones she has either to find it again or refund its value. The tools employed in diamond cutting are very similar in appearance to those used in the first process, that of diamond splitting. In both cases diamonds are used as knives after having been firmly fixed into the tip of pear-shaped tools. The women hold in the left hand the rough diamond they wish to cut, which has also been firmly fixed into a wooden frame. Little jets of gas are always kept burning on the various tables ready to be used at any moment when melted wax is necessary. The only real difference in the two processes of diamond splitting and diamond cutting lies in the fact that whereas the men who split the diamonds use pressure on one spot only (where the flaw occurs) the women devote themselves to rounding the whole stone, and carefully cutting off all angles to be seen on its surface by means of the sharp diamonds they hold in their right hands. Occasionally they have very large diamonds to cut, which take a great deal of time, but an ordinary stone weighing about 10 carats would not take so very long. When the diamond has been sufficiently cut and rounded, it is then ready for the third and last process, that of polishing. This work requires a great deal of time and skill, and is performed entirely by machinery, a steam-engine supplying the motive power for all the iron discs. The process consists in giving to the rounded diamonds what is termed, in technical language, their necessary "sides." All diamonds are divided into two classes, "brilliants" and "roses," although the only real difference between them lies in the number of "sides" they individually possess after having been polished in one of the many diamond factories. A

"brilliant" must possess fifty-eight "sides" (a few years ago the lowest number was sixty-four, for there are fashions in diamond cutting), but a rose need only possess twenty-four "sides." Another (though slight) difference between them is, that a brilliant is pointed at both ends, while a "rose" diamond has one end flattened and the other pointed. When the diamond is ready to be polished it has first to be soldered into a pear-shaped frame made of zinc and then dipped into a preparation of oil and diamond dust before being fastened, with three others, into a strong frame placed in close proximity to an iron wheel. This little disc is then set in motion, by connecting it with the great engine, and the wheel immediately turns at the rate of 2,000 revolutions to the minute. As it revolves, the four diamonds set in the adjacent frame are gradually polished by means of the friction produced on their surface by the particles of diamond dust still adhering to the oil into which they had been previously dipped. Only one portion of a diamond can be polished at once, and consequently, when this part has been dealt with, the stone has to be re-soldered, so that another portion of its surface may be subjected to the friction of the wheel. The process of re-soldering takes place about twenty times in the case of every brilliant, before it can be considered to be thoroughly polished, and to have acquired all the necessary fifty-eight "sides." The "rose" diamond, with its smaller complement of twenty-four "sides," needs to be re-soldered only about six times.

During the last year the press, both in South Africa and Europe, has devoted considerable attention to the discussion of projects having in view the establishment of a diamond polishing industry in Cape Town, Johannesburg, and other places, but such projects are not regarded seriously in Amsterdam. Wages paid in the diamond industry at Amsterdam are estimated to have amounted to £1,700,000 in 1905.

INLAND REVENUE.

The figures given in the fiftieth report of the Commissioners of Inland Revenue, just issued, lend some support to the contention that temperance is making headway, and that the diminution in the consumption of beer and spirits which has been so noticeable in recent years is not, as it is sometimes said to be, due only to hard times. Industrial conditions have been good for some time past, and if increase or decrease in the consumption of alcohol depended only upon good wages the figures in the present report would show expansion in the beer and spirits consumed *per capita*. The number of proof gallons of colonial and foreign spirits imported into the United Kingdom in 1906-7 was less than in the preceding year—8,129,503 gallons as against 8,228,435; the quantity of home made spirits retained for consumption was less *per capita* in 1906-7 than in 1905-6—·74 as against ·75; the quantity of beer retained for consumption in 1906-7 was 27·81 gallons as against 27·90 in the previous year, and 30·49 in 1896-7. The decline in 1906-7 was smaller than in previous years, but there was a decline.

Some interesting particulars are given as to the Income-tax. The net yield of the tax for the year 1906-7 was £31,891,949, an increase of £597,197 compared with the previous year. The certified gross income of the 379,456 payees was £107,022,457, and of these 21 paid on incomes exceeding £50,000. Profits from British, Indian, Colonial, and Foreign Government securities show an increase of £8,428,000, or 21·9 per cent. over the decennial period 1896 97—1905-6. The assessments on the incomes from British Government securities in 1905-06 was £15,993,607, as against £13,641,207 ten years earlier. The assessment on those from Colonial Government securities comes next, and amounts to £13,906,601, then India £8,862,807. These last figures show little increase upon those of 1896-97, which were £8,065,866, and the African assessment is considerably less now than it was ten years ago—£541,896 as against £727,826. £30,932,067 represents the total income derived from Indian, Colonial, and foreign Government securities in 1905-6, but the total of *all* income from abroad that could be identified in the statistics of the income tax was £73,899,265 against £66,062,109 in 1904-5. Businesses, Concerns, Professions, &c., show an increase of £131,566,000, or 34·8 per cent. during the ten years. On a more particular comparison, railways in the United Kingdom show for the same period an increase of £3,700,000; mines, £9,491,000; gas works, £1,884,000; water works, £1,801,000. It is very noticeable that salaries of Government, corporation, and public company officials increased in the ten years from £56,449,000 to £93,186,000, or 65 per cent.

The extent of the fall of rents of agricultural land, and the absorption of land in the neighbourhood of large towns for building purposes, is shown in the figures under "Lands," which show a decrease of £2,649,359, or 4·8 per cent. The principal decreases were in Kent (outside the metropolis), amounting to 11·1 per cent.; Essex, 13·5 per cent.; Suffolk, 13·7 per cent.; Norfolk, 10·1 per cent.; Somersetshire, 8·5 per cent. On the other hand, "Houses" show an increase of £46,711,940, or 29·4 per cent. in the ten years accounted for by the erection of new buildings and increased rentals of old ones. The increase was distributed among the three countries as follows:—England, £41,482,930; Scotland, £4,476,342; Ireland, £752,665. The increases mainly occur in the Metropolis, 17·2 per cent.; Surrey (outside Metropolis), 57·5 per cent.; Middlesex (outside Metropolis), 75·5 per cent.; Essex, 74·6 per cent.; Northumberland, 48·4 per cent.; Durham, 42·6 per cent.; Kent (outside Metropolis), 42·3 per cent. The prosperity of the country generally is indicated by the figures

relating to profits from businesses, concerns, professions, employment (except those of a public nature, and certain interest). The gross amount of income under this head brought under review of the Department for the year 1905-6 was £508,664,345, being an increase of £131,565,580, or 34·8 per cent. over the amount of 1896-7, and of £4,096,546 over that of 1904-5, or ·8 per cent. The increase was distributed among the three countries as follows:—England, ·9 per cent.; Scotland, 1·0 per cent.; Ireland, 2·7 per cent.

AGRICULTURAL CO-OPERATION IN GREAT BRITAIN.*

The problems to be solved are the limitation of the rural exodus and the rehabilitation of rural life.

The economic aspect of the problem is how to make farming pay on a small as well as on a large scale. The economic forces at work against the farmer are the competition of new countries, made possible by the development of cheap transport, and the competition of older countries in which an agricultural revival has taken place. In the latter case, co-operation has been one of the chief factors in the success of our competitors. By its means farmers are enabled to obtain goods of guaranteed quality and purity; to purchase their requirements more cheaply, and so to decrease the cost of production; to bulk the consignment of goods purchased and goods sold, and so to reduce the cost of transport; to get into closer touch with the consumer, and so to secure a larger share of the profit upon goods sold; to place large quantities of produce of uniform quality upon the market, and so to meet the requirements of a wider circle of customers and to obtain better prices.

Co-operation has other advantages which should commend it to us. Among them are the development of character and of the intellect. Farmers as a class are intensely conservative, wedded to the ways of their forbears and jealous and mistrustful of one another. Intercourse at the meetings of their societies tends to break down the barriers of mistrust and jealousy which separate farmer from farmer, to broaden their outlook, and to teach them no longer to regard the welfare of their neighbours as detrimental to their own; while the discussions upon business matters have a stimulating effect upon their minds, and arouse a spirit of inquiry and a desire for knowledge.

While there are instances of agricultural co-operation in Great Britain of many years' standing, there was no systematic effort to promote it until the Agricultural Organisation Society was formed in 1901. It is true that co-operation was part of the programme of the National Agricultural Union, of which Lord Winchilsea was the founder and the inspiring spirit, but it was never seriously taken in hand. In 1900, in addition to the National Agricultural Union, another body had come into existence to promote agricultural co-operation, viz., the British Agricultural Organisation Society. This was done, and the results obtained have been eminently satisfactory.

The number of agricultural co-operative societies affiliated to the Agricultural Organisation Society had reached 153 at the end of June, 1907. These included 109 societies for the purchase of requirements and sale of produce, 14 dairy societies, 13 credit societies, 4 allotment societies, 2 motor-service societies, 2 fruit-grading societies, 7 miscellaneous societies, and 2 federations.

The membership of the societies in June, 1907, was roughly estimated to be 10,000, and their turnover in 1907 is expected to reach £450,000.

The material benefits to the members of the societies have been considerable, but it is impossible to estimate them with any accuracy. In the purchase of requirements they have secured reductions in price averaging probably about 15 per cent., and the benefit of obtaining goods of guaranteed purity is fully equal, if not superior, to that of the reduction in price. The sale of produce has not been developed to the same extent as the purchase of requirements, but where it has been carried out the net prices to the farmers have been substantially increased.

There has been ample evidence of educational as well as material results. It is the experience of the societies that co-operation has produced a more neighbourly feeling amongst the farmers, who become more ready to interchange ideas and place their knowledge at each other's disposal. With this has come a greater desire for knowledge.

An important form of co-operation is co-operative credit. Village banks on the Raiffeisen model were promoted by the Co-operative Banks Association before the formation of the Agricultural Organisation Society. In 1903 the two associations were amalgamated. In June, 1907, there were thirteen village banks affiliated to the Agricultural Organisation Society. The object of these little banks is to provide their members with capital for reproductive purposes at low rates of interest. A Central Co-operative Agricultural Bank has been formed for the purpose of financing the village banks.

For the success of the small holdings system co-operation is essential. Without it the small holder is at the mercy of the middlemen from whom he purchases his requirements and to whom he sells his produce. Co-operation places the small holder on an equal footing with the large farmer in his dealings, and provides him with the use of cheap loans for economic and productive purposes.

The intense conservatism of the farmer makes the work of organisation very difficult. His naturally suspicious temperament adds to the difficulty, as he is apt to imagine that those who are urging him to co-operate have an axe to grind in doing so. Gradually the Agricultural Organisation Society has been able to remove this suspicion from the farmers' minds, and

* Paper read by Mr. R. A. Yerburgh before Section F of the British Association, at Leicester.

the success of the co-operative societies is breaking down their disinclination to adopt new methods.

The chief difficulty which now confronts the agricultural co-operative movement is that of obtaining the necessary funds for carrying on propagandist work. The Agricultural Organisation Society feels that it may reasonably look to the Government for assistance. The Small Holdings Committee recommended that the society should receive a grant from the Board of Agriculture, and in the Small Holdings and Allotments Bill the importance of agricultural co-operation in the development of small holdings is recognised. In Ireland the Department of Agriculture makes a grant to the Irish Agricultural Organisation Society proportionate to the subscriptions which it receives from other sources, and it would greatly help to foster the movement in Great Britain if the Board of Agriculture would make a similar grant to the Agricultural Organisation Society.

NEW DOCK AT SOUTHAMPTON.

The new dock about to be constructed at Southampton will be the deepest open dock in the world. Exclusive of the quays and cargo sheds the dock will cover an area of sixteen acres, lying between the Empress Dock and the Trafalgar Graving Dock. The water area will form a parallelogram 1,700 feet by 400 feet. The depth of the new dock will be eventually dredged out to a minimum depth of 40 feet, increasing to 53 feet at high water. There will be berths inside the dock for four vessels each about 800 feet long, and these will, of course, be able to enter and leave at any state of the tide. Outside, the deep-water quays in the Test already furnish a depth of 32 feet at lower water, but the new dock is designed to give more than this, in fact greater depth will there be secured than is obtainable anywhere else. No ship in existence requires so great a depth of water as 40 feet, but it is notorious that the size of vessels is increasing so fast that a margin for future development is absolutely necessary. The new dock opens into the Test, where four new quays are to be constructed, two of about 700 feet in length and two of 500 feet. Southampton possesses very exceptional advantages as a port owing, first, to its sheltered position, and, next, to double tides, which not only extend the normal period of high water to four hours, but also restrict the ordinary range of spring tides to 13 feet, and in addition render unnecessary the provision of locks. Since 1843, the date of opening the first dock, both wet and dry docks have been added, and the acquisition of the port by the London and South-Western Railway Company, in 1892, has led to still greater developments. The Prince of Wales Graving Dock, opened by the King in 1895, and the Trafalgar Graving Dock, constructed since that date, and brought into use quite recently, are 750 feet and 875 feet long respectively. Other improvements, too numerous to mention here, have been carried out by the company, and the new dock, the site for which has already been cleared, will not only bring the existing accommodation up to date, but enable Southampton to enter into serious competition with the port of London, whose circumstances have suffered owing to the long delay in carrying out even a part of the recommendations of the Royal Commission of 1900-1902.

OUR FOOD SUPPLIES.

The report of the Board of Agriculture and Fisheries upon agricultural imports contains some striking figures with regard to the growing dependence of the population of this country upon foreign supplies of food. Taking the last 25 years the total imports have increased from 444,000 tons to 1,078,000 tons. While our foreign supplies have increased from 415,000 tons to 838,000 tons, the Colonial supplies have gone up from 29,000 tons to 240,000 tons. Or, to put it in another way, Colonial supplies have risen from 6 per cent. to 22 per cent. Of the total imports the greatest relative increase is in the imports of dead meat, of which we consume twice as much per head as we did 20 years ago. In 1886 the proportion per head of fresh beef, mutton, and pork was 4·8 lbs., last year 25·9 lbs. All other descriptions of dead meat showed increase, and if the total is taken, it has increased from 20·7 in 1886 to 47·3 in 1906. The consumption of imported bread stuffs has increased in a much less degree notwithstanding the reduction of home supplies. The total home crop has decreased from about 1,850,000 to 1,350,000 tons, yet we find that the proportional quantities consumed per head of the population of corn grain, meal, and flour imported, which in 1886 was 59 lbs., in 1906 was only 62 lbs. although in 1894 it had risen to 117 lbs. Taking these figures in conjunction with those given above relating to meat, the conclusion seems to be that the proportion of meat to bread in the dietary has substantially increased, or in other words that the average standard of living has risen during this period. The figures in relation to butter and margarine appear to support this contention. The proportion per head of the population of butter and margarine used has risen from 7·5 in 1886 to 13·9 in 1906. So with eggs, which have risen from 29 per head of the population in the earlier year to 52 last year. It is only cheese which shows comparatively little expansion, as from 5·4 lbs. per head 20 years ago to 6·8 last year. Having regard to the ever-growing demand for milk in the United Kingdom, and the fact that only a quite insignificant quantity is imported, it is pretty safe to say that the quantity of home cheese sold is not to any appreciable extent larger, notwithstanding the increase of stock, than it was 20 years ago, so that we must assume that less cheese is being eaten, meat apparently having taken its place. If that be so, we have a further indication of the growing prosperity of the country.

There has been a remarkable increase in the imports of Colonial butter. In 1886 the imports from all countries amounted to 78,800 tons; last year they had increased to 212,100 tons; but whilst foreign imports had increased from 76,950 tons to 159,300 tons, the Colonial supplies increased from 1,850 tons only to 52,800 tons. Imports of butter from the Colonies, which barely exceeded 2½ per cent. of the total in 1886-8, had reached 25 per cent. in 1904-6. From the details given in Table CI, it would seem that the supplies from Denmark, France, Holland, Norway and Sweden have reached their maximum. Those from France, Sweden, and Denmark were considerably smaller in 1906 than in 1902. On the other hand, the imports from Russia increased from 490,091 cwts. to 605,549 cwts., and from the United States of America from 54,458 to 157,312 cwts. Amongst the Colonies, the increase of the Australian import is the most noticeable. In 1902 it was only 89,397 cwts., in 1906 it had risen to 561,114 cwts., the increase being principally from New South Wales and Victoria. On the other hand, the imports from Canada fell from 285,765 cwts. to 190,968 cwts. It should have been said that the imports from New Zealand increased from 157,993 to 311,672 cwts.

Over 2¼ thousand million (2,264,887,000) eggs were imported in 1906, being rather more than in 1905, but less than in any of the years 1902-3-4. Russia sends more than one-third of the total, Denmark, Germany, Belgium, and France appearing as the other chief contributors. The stationary character of these imports would seem to indicate that poultry farming is on the increase in the United Kingdom. The appearance of Australia among our sources of supply for eggs is a noteworthy feature, Victoria sending 220,000 and South Australia 728,000 last year. Canada, which has entered this trade in recent years, does not seem to be maintaining her footing, the number sent in 1906 being less than half that received in 1902 or 1903. Apart from bananas, which, being recorded in bunches, cannot enter into comparison, oranges represent nearly half of our total supply of fruit from abroad. Apples, however, stand a good second, of which almost exactly half came from the United States, and about one-third from Canada. Australia sent 157,000 cwt., largely from Tasmania, while Portugal sent nearly as much (168,000 cwt.) as all other European countries put together. Spain and Portugal account for 95 per cent. of the grapes received, the Channel Islands, with 16,000 cwt., being the principal contributor to the remainder. More than half of the pears received come from France, and four-fifths of the cherries.

BELGIAN TECHNICAL SCHOOLS.

The prosperity of Belgium, which is advancing rapidly from year to year, is undoubtedly due to the technical teaching which is prominent in the diversity and numbers of its institutions. These schools, created and maintained by the Government, are under the general supervision of the Department of Commerce and Labour, which appoints a Board of General Supervisors, whose duty it is to see that the teaching is of a high standard, as well as to look into the sanitary and hygienic arrangements of the various schools. Belgium enjoys the distinction of being the first country to organise domestic training schools, the first being established in 1889. According to the American Consul at Liège, this system comprises in its practical curriculum maintenance and cleanliness of dwellings, furnishings, laundry work, cutting, fitting, making, and repairing ordinary garments, cooking, and, in the rural districts, gardening, dairy work, and the care of poultry. The theoretical teaching consists of lectures on hygiene, domestic economy, care of children, and sick nursing. This particular training is intended for the children of the working classes, the object being to prepare the pupils for the economical management of a house, as a mistress or as a servant. In the more advanced schools, termed professional domestic schools, the theoretical and practical teaching are equal, and includes designing, cutting, dressmaking, millinery, artificial flower making, lace making, embroidery, china painting, commercial book-keeping, typewriting, domestic economy, &c. The practical effect of this system not only enables a girl to gain a livelihood by the application of her knowledge in the various branches taught, but is particularly emphasised in housekeeping. While the Government has legislated against the employment of women underground, they assume important places in the large manufactories, and work side by side with the male *employés*, showing equal ability. Many of the large workshops give technical lectures and demonstrations expressly for the female employee who is unable to take advantage of the technical course offered to boys. In training boys for professional and industrial work, attention is given to the demands of the various localities. The various schools are as follows:—Mechanical and electrical engineering, iron and steel, wood cutting, carpentering, joining, plumbing, watch making, jewellery making, firearm manufacturing, book-binding and gilding, painting, designing, engraving, spinning and weaving, dyeing, tanning, basket and lace making, upholstery, tailoring, telegraphy, music, &c. While the practical work of these institutions is the same as in the actual workshops, the theoretical training is intended to meet what the workshop does not supply. Apart from the Government technical training schools, private institutions have been established, and are partly maintained by private subscriptions. These, however, look for help to the Government. Liège, since the fourteenth century, has been universally known for the manufacture of firearms. It has kept pace with the various evolutions in this industry. The well-known School of Arms in Liège turns into the local workshops annually, young men already fitted to apply them-

selves practically to any branch of the firearm trade. One of the practical requirements before graduation is that the pupil must not only be able to make any of the various parts of a gun, but must be able to put these parts together with facility. In theory and practice they are as perfect as age will permit, and yet they must enter the factory in the capacity of an apprentice and await the recognition of the foreman. The system of education forms a capability that is sought for by many countries, and the workman after leaving the school of arms can readily find work either at home or abroad. Many practical gunsmiths have attached to their homes a small workshop where during their spare hours they work under the piecework system, and are, therefore, enabled to earn more money. This class of labour is always in demand, and at no time need the firearm workman be out of employment. The School of Textiles is an institution where teaching has brought out the manufacture of cloth and all branches attached to that industry to a high state of perfection. Year after year the cloth manufacturers in other countries apply to this school for a competent man to serve them as foreman or superintendent. In Belgium itself the pupils at this institution are immediately taken up by the local manufecturers and their future is assured. The Government, to encourage application, gives yearly a money prize to pupils having distinguished themselves at the school, this being intended to meet the expenses of a journey abroad. The same conditions prevail at the School of Mining, and all the other schools. Technical education in Belgium has for its object to assist the employer and employed alike. The present condition of both is highly satisfactory, and the future points to a substantial advancement. The country is tranquil, the working classes are increasing their savings annually, a spirit of contentment is everywhere manifest, which condition of affairs guarantees uninterrupted labour. Lockouts and strikes are rare, while the question of the unemployed is absent. All workmen are more or less skilled, and their labour wins a compensation satisfactory to them. The continued industrial and commercial advancement of Belgium stimulates the demand for labour, and the labour, owing to technical education in all its branches, readily meets these demands.

CALCIUM: ITS PROPERTIES AND POSSIBILITIES.*

General Properties.—Calcium is a silvery white metal readily oxidised in moist air. It is very light (sp. gr. 1·52), fairly malleable, has a high specific heat, and is a good conductor of electricity. It is about as hard as aluminium, but at 400° C. becomes as soft as lead. It is volatile, and can be sublimed *in vacuo* between 700° C. and 800° C., and melts at the latter temperature. It is a very powerful reducing agent.

Calcium Alloys.—The chief effects of alloying calcium with other metals are to produce brittleness, crystallisation, and hardness; to promote oxidation and disintegration on exposure to air; to confer the power of decomposing water and in other ways increasing the chemical activity.

The author's experiments confirm Roberts-Austen's observation that the presence of small amounts of metals of high atomic volume will cause deterioration of the physical properties of metals of low atomic volume. The atomic volume of calcium is high (25·4), and the effect of small amounts on other metals is decidedly prejudicial, provided that the metals in question are pure. The experiments were conducted in a converse manner to Roberts-Austen's, *i.e.*, the constant was a metal of high atomic volume (calcium) instead of being low (gold). In the course of the work the following observations were made. When an alloy is made of calcium and some metal which possesses a chemical property in common with it, an increased activity in the manifestation of that property is noticed in the alloy. This increase appears to be greater than would be obtained by the simple admixture of a more active metal, the presence of calcium usually increasing the activity of the other metal. In some cases the alloy is more active than either of its constituents.

Further, the chemical properties of calcium appear to be more pronounced in an alloy with a metal having an atomic value closely approaching that of calcium than they are in an alloy of the same percentage with a metal having a much lower atomic value. The two metals in question should be about equally active when unalloyed in the particular property with respect to which they are to be compared. It is probable that both these principles are general, and not confined to calcium, although more extended research on these lines would be desirable.

Industrial Possibilities. — The most promising applications of calcium are as a reducing agent and for the refining of metals. In the latter case it acts in three distinct ways:—(1) By reducing oxides and sulphides; (2) by eliminating dissolved gases; (3) by forming compounds with certain impurities, thus rendering them less deleterious. All three modes of action are strikingly shown in the case of copper. A suitable addition of calcium will remedy "dry" or "sulphury" copper, give a sound casting, and give a soft and tough ingot with prohibitive proportions of bismuth or antimony, besides restoring ordinary overpoled copper to tough pitch. If excess of calcium is present, however, it induces brittleness on its own account. With one or two doubtful exceptions, no alloy of calcium has shown any promise of commercial utility so far as physical properties are concerned, its only likely application in this direction being its hardening property.

* Abstract of a paper read by Arthur E. Pratt, B.Sc., A.R.S.M., read before Section B of the British Association, at Leicester.

ARTS AND CRAFTS.

Pottery and Porcelain.—The pottery and porcelain trades perhaps more than any others have made great strides in recent years. The advances in chemical science have rendered many things comparatively simple which in days gone by would have been difficult, if not impossible. Old-established factories famed for productions in one exclusive style have been trying new experiments and doing work quite unlike what we should, from their traditions, naturally expect from them. And this has been the case not merely in England but all over the continent. At the time of the last Paris Exhibition in 1900 it seemed as though nearly all the makers in Europe were working on more or less the same lines. Crystalline glazes were the order of the day, and everyone was producing them more or less successfully. There were differences, of course, between the crystalline glazes of, say, Sèvres and Copenhagen, but they were not such as to strike the quite untrained observer, and the effort was all in the same direction. Now that the exhibition is a thing of the past, and that there is no enormous international exhibition looming in the immediate future, the different factories are, if not exactly returning to their old paths, at any rate working more on their own special lines.

Sweden.—The two big works in Sweden, Rörstrand and Gustafsberg, appear to have practically given up making crystalline glazes. In the case of Rörstrand at least this is to be regretted, as some of their efforts in this direction and in *sang de bœuf* were really very successful. A good deal of the work being done at this factory to-day is not unlike what we are accustomed to associate with Copenhagen. It is pale in colour and delicately painted for the most part, but the distinguishing feature of the Swedish pots is the use of modelling. The neck of the vase is very often adorned with, or even formed of, delicately modelled flowers or leaves. The forms are generally very happy, especially when, as frequently happens, the back side of the leaf is represented, slightly bent over so as to make a decorative feature of the mid-rib. A recent achievement at the same works, of which the inventors are naturally proud, is the production of a fine glaze which is practically black in colour. They are only beginning to use it, but it promises to lend itself to decidedly novel effects.

Gustafsberg has been developing almost exclusively the kind of work which can be produced at a fairly low price. They are no longer making imitations of Wedgwood, but are proceeding according to modern Swedish taste, and some of their very cheap dinner services, &c., are exceedingly tasteful. In their ornamental ware they are making good use of the practice of coating the vessel with slip and then scratching out the ground. They are also turning out a good deal of heavy-looking stoneware decorated with various colours.

By the way, it is interesting to note that in both these factories the artist in chief is a man who did not begin life as a designer for pottery, nor, indeed, as a designer at all, but as a purely pictorial painter, which accounts for some of their failures as well as for their successes.

Copenhagen.—At Copenhagen, the Royal Porcelain Works have been pursuing the even tenor of their way. They are still making experiments in crystalline and other glazes and steadily progressing in this direction; but the bulk of their work is naturally, as it has been for so long, painted and modelled porcelain. They are constantly adding to their menagerie astonishingly life-like animals, which have the additional merit of showing to great advantage the perfection of the material in which they are executed. The greater part of the work, of course, is in the pale colours with which we are familiar, but they have produced also vases in more brilliant blue and in a rich green. A new departure of theirs is a series of figures in old Danish costumes, brightly painted in on-glaze colours. Something of the kind was done in the factory years ago, but these figures are entirely modern in feeling.

The Royal Works have made their reputation for a particular kind of work, and they very naturally produce what is expected of them, but the case is very different with the more recently established "Aluminia" earthenware factory, which is under the same direction. These works have only been established about four or five years, and they are already doing very good work. The most characteristic vases are painted in deep rich blue and green on a creamy body. They do use other colours, notably yellow and red, but it is the blue and green which are most generally employed, and, on the whole, most satisfactorily. The painting is large in scale and in a sense, rather coarse, as befits the coarse material used and the large size of the objects made; but one has only to put a piece of Aluminia *faïence* side by side with a piece of real or affected "peasant" pottery to see that the painting is quite accomplished and that the design has received an amount of consideration and a care which we look for in vain in the more primitive work. Until lately the factory had confined its energies to the production of pots, vases, and dinner services, but a short time ago they began making tiles. Their first piece of work of this kind was for the decoration over the doorway of the Tropical Bird House in the Copenhagen Zoological Gardens—and a very satisfactory piece of work it is. The design consists of peacocks and other birds surrounded by a certain amount of green foliage—and the whole thing, which is mainly in blues and greens with only a few patches of other tints, makes a fine bit of colour. It is interesting to note, by the way, that these are 4-inch tiles—a size which seems very popular just now in Northern Europe.

Amongst the mass of work being turned out by the various factories in Denmark, it is interesting to see the rather accidental looking lustre pieces by

Hermann Kähler—who seems to be still working very much on the lines he indicated at Paris in 1900.

Delft.—Delft ware we are apt to look upon as being practically confined to vases, plates, plaques and tiles painted in blue, or perhaps brown or manganese on a white ground—and, of course an enormous trade is done in such things, but the energies of Messrs. Joost Thooft and Labouchère are covering a very much larger field. The panel in *opus sectile* at the Paris Exhibition was the beginning of what is now quite an important branch of their work. The material, which is primarily intended for outside decoration, is made in a good range of low toned, rather earthy colours, the pieces are cut out of the wet clay, and the painting, where painting is necessary, is done in slip. If we miss a brightness of colour in the finished work, that is somewhat made up for by the absence of the shiny quality of glaze—never very pleasant in wall decoration—and by the feeling that there is no danger of the material crazing or playing tricks after long exposure to the air. The designs executed by this method are many of them very elaborate, and include figure subjects—and the fact that the pieces, cut before firing, join together with only a very narrow cement outline, proves that the makers have their material well under control.

This *opus sectile* is the biggest departure from the old methods of work which is being made at the present time—but, of course, for some years past crystalline and dull lustre tiles, some of them very beautiful in quality, have been made at Delft—and the raised outline process is used to good purpose, sometimes with a sort of encloisoned jewel effect which is quite fascinating.

As regards vases, an effort has been made to revive the old Delft ware painted on the unbaked tin enamel, but it seems that the demand is all for the more pictorial painting on a white body. Some vases have lately been made of a sort of cream parian body, decorated with patterns in green and gold. The green, which is only used in fairly small touches, is of the same consistency as the body, and the gold is put into the incised lines which give the outline of the pattern. The effect is very fresh both in colour and design.

In view of our somewhat feverish haste in this country to supply craft teaching at all costs for all kinds of work, and to assume that the school of art, or the craft school, is, under existing modern conditions, the proper place in which workers in the more artistic crafts are to get their training, it is rather interesting to note how little agreement there is on this point in some of the big European pottery works. At one place we are told that all the paintresses come direct from the local school of art to the factory, after passing a competitive examination. At another equally large and progressive factory the painters are taken into the works as soon as they leave the elementary school, with no art school training at all, and receive the artistic training necessary for their work in the factory itself. In both cases the work turned out is excellent in quality, and the result would seem to prove that there is not one universal solution of the problem of art education for trade workers.

OBITUARY.

ALFRED BACHE, M.I.M.E., M.I.C.E.—Mr. Bache, late Secretary of the Institution of Mechanical Engineers, died at Penzance on the 6th inst. Mr. Bache, who was born at Birmingham in 1835, was the son of a dissenting minister. He was educated at the Edgbaston Proprietary School and the Queen's College, Birmingham, and graduated at the London University in 1854. He became assistant to the secretary of the Institution of Mechanical Engineers, and in 1884 was elected secretary. He continued to hold this post until 1898, when he resigned on account of ill-health and went to live at Penzance, Mr. Bache was an accomplished musician and a linguist with a knowledge of the Greek, Latin, French, German, Italian, Swedish, and Norse languages. He was elected a member of the Society of Arts in 1887.

GENERAL NOTES.

BRAZILIAN DIAMONDS.—In his report on the trade of Bahia (Cd. 3283-162), Mr. Consul O'Sullivan-Beare refers to the diamonds found in many districts throughout the State of Bahia. The white diamonds of this district have long been celebrated for their matchless colour and fire. The finest stones are characterised by the existence of a slightly bluish tint, which is found in no other stones, and which places the Bahia diamonds apart from and above all others. In former days, diamond mining was a very important interest in Bahia, but the development of the Kimberley Mines had the effect of stifling the industry in Bahia. At the present time there is no systematic mining for diamonds carried on there, the industry being wholly in the hands of the individual "Garimperios" (washers), who work in a most primitive and haphazard fashion, each man for himself. It is only in Bahia the very valuable carbonatos, or so-called black diamonds, are found. These stones owe their commercial value to their intense hardness, and are used as tips for rock drills. Being very rare they are considered more valuable weight for weight than diamonds of pure water. They are found usually associated with diamonds, but strictly speaking they are not diamonds but a distinct variety or amorphous carbon. Most of the diamonds and carbonatos exported from Bahia are smuggled out of the country in order to avoid the 5 per cent. export duty, suc smuggling being a very easy accomplishment owing to the small bulk occupied by the stones.

Journal of the Society of Arts.

No. 2,863. VOL. LV.

FRIDAY, OCTOBER 4, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

CANTOR LECTURES.

Mr. F. HAMILTON JACKSON'S Cantor Lectures on "Romanesque Ornament" have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Society of Arts, John-street, Adelphi, London, W.C.

A full list of the Cantor Lectures which have been published separately, and are still on sale, can be obtained on application to the Secretary.

"OWEN JONES" PRIZES FOR INDUSTRIAL DESIGN.

The Council of the Society of Arts hold a sum of £400, the balance of the subscriptions to the Owen Jones Memorial Fund, presented to them by the Memorial Committee, on condition of their spending the interest thereof in prizes to "Students of the Schools of Art who, in annual competition, produce the best designs for Household Furniture, Carpets, Wall-papers, and Hangings, Damasks, Chintzes, &c., regulated by the principles laid down by Owen Jones."

The prizes will be awarded on the results of the annual competition of the Board of Education, South Kensington. Competing designs must be marked, "In competition for the Owen Jones Prizes."

No candidate who has gained one of the above prizes can again take part in the competition.

The next award will be made in 1908, when six prizes are offered for competition, each prize to consist of a bound copy of "The Leading Principles in Composition of Ornament of Every Period," from the Grammar of Ornament, by Owen Jones, and the Society's Bronze Medal.

INDIAN OCEAN METEOROLOGY AND ITS RELATION TO THE SOUTH-WEST MONSOON.

I wish to introduce to the members of the Society of Arts the subject of Indian Ocean Meteorology, seeing that it bears most forcibly on the agriculture and commerce of Western India, and deals with the failure, in 1905, of the south-west monsoon in different parts of India, a failure which has caused much anxiety throughout the whole of the Empire.

It is not my desire or purpose to go into the details of the widespread hardships and distress which a complete failure of a monsoon would entail; almost everyone knows only too well the heartrending history of the last famine in the Bombay Presidency. My object is to draw the attention of members to the meteorological variations of the Indian Ocean, in order that the subject may be discussed in such a manner as to induce members of the Indian Section, who are thus more directly interested in Indian affairs, both agricultural and commercial, to find a way to approach the Governments of India and of Mauritius to consent to the outlay of sufficient funds with the view of learning more of meteorology of the lands and oceans, which will be mentioned in the body of this paper, than is at present known. It is only by means of controversies and discussions among men of science and of acquired experience, that any really tangible matter can be obtained with which to construct a reasonable theory as to the causes of the monsoon rainfall, and of the reasons for its periodical failure. Unfortunately such discussions are few and far between, especially as regards nautical men, who are doubtless better able to throw light on the matter than any others. Having a record of twenty-five years under sail and steam in the Indian Ocean, I have necessarily acquired considerable experience in all matters climatic connected with this part of the globe.

There is not the shadow of a doubt that the atmospheric conditions of the Indian Ocean and Arabian Sea have considerably changed of late years, and the changes are probably still going on, but are unnoticed and unrecorded for want of more extended means of observation. I have often heard it asked, Is the desert creeping on, is it gaining in area as the world grows older? As time goes by will the coast line of Sind, Kathiawar, and Bombay become a rainless zone as is the Arabian coast on the west side? It is extremely difficult to assign the cause or causes of the partial or complete failure of monsoon rains, or of a late or early monsoon, but a combination of probable causes, however distant apart, may be put forward and discussed on their respective merits, from which some fairly reliable theory may be arrived at. The solution of the question of monsoon failures may even be found outside of India, and far distant from its shores. I believe the theory of excessive snowfall in the Central and Western Himalaya regions and its probable deterrent influence on rain-bearing currents was put forward by Mr. Blanford some years ago, and was for some time discredited. The failure of monsoon rains up to as late at least as the 8th September, 1905, when I left Bombay, has caused this snowfall theory to be revived with vigour. It has been remarked during the past few years that the winter and spring snowfalls do produce an effect on the monsoon rain-bearing currents. I believe the theory in connection therewith is this, if there is a great snowfall at these two periods of the season, and if that snowfall extends lower down the ranges and approaches the plains, it has a disturbing influence on the monsoon current, and causes drought. There is, however, another theory which we will do well to examine. In May, 1897, Sir John (then Mr.) Eliot, late Meteorological Reporter to the Government of India, in a tentative forecast of the expected monsoon, laid some stress on the normal or abnormal conditions of the south-west monsoon. At the time I supported his views in my "New Handbook of the Indian Ocean," and am now more convinced than ever that if a strong south-east trade is experienced up to near the equator a like south-west monsoon will blow to the north, and *vice versâ*. As far back as 1863, the late Dr. Meldrum, F.R.S., Director of the Royal Alfred Observatory at Mauritius, said: "Is not the south-west monsoon of the northern hemisphere from April to October a continuation of the south-east trade winds? When the south-west monsoon prevails in the northern hemisphere the south-east trade blows down to the equator, or beyond it, and the southern limits of the monsoon are in the immediate neighbourhood of the northern limits of the trade, both winds moving in a northerly direction." In August last, a writer in the *Pioneer* remarked that India was still floundering on the confines of meteorological science. May this not also be said of places in the immediate neighbourhood of India, and of localities within a certain radius of India? The snowfall theory more fully developed both in the northern and southern hemispheres may reveal much. This theory is credited with pretending that the snowfall has a deterrent effect on the rainfall of Upper India, and it may also be extended to the southern hemisphere, where excessive snowfall in the south Indian Ocean may also have the same effect on the rain-bearing currents coming up the Arabian Sea. One noticeable feature of the south-east trade in 1905 was its weakness from the equator to 20 degrees south, or say as far south as Mauritius, and the south-west monsoon has been of about equal force at the north. At Mauritius the wind as usual veered to south-south-east and south in June, and although light throughout June, July, and August, the polar winds were exceptionally cold throughout the island. The cold wind was felt and remarked, but no one ever gave a passing thought as to why it should have been so experienced. If we take, however, a glance at the map it will be at once seen that, directly facing the Bay of Bengal and Arabian Sea, we have numerous groups of snow-covered islands in the South Indian Ocean—namely, St. Paul, Amsterdam, Kerguelen, McDonald, Crozet, and Prince Edward Islands. Now, all these islands have heavy snowfalls in winter, and numerous icebergs are often grounded in soundings in their neighbourhood—especially Kerguelen Island—and icebergs have even been reported north of the 40th parallel of south latitude. Kerguelen Island is almost on the same meridian as Bombay, and the Crozet group is in a like position as regards Cape Guardafui. The cold wind blowing from the Pole is felt in Mauritius and neighbouring islands more or less according to the conditions of the snowfall and the quantity of ice to the south. May not this same current travelling toward the equator and beyond it have some disturbing effect on the rain-bearing clouds moving up the

Arabian Sea and towards Western India, so that the monsoon may be checked by excessive and late snowfall in the north, and by the same cause in the south so far as the Arabian Sea current is concerned? The distance of the islands I have mentioned from the south limit of the south-west monsoon regions and the deflection of cold currents from the southern ocean by intervening lands may be against my argument. but, taking into consideration that in these parts we know so little of aerial observations, and as we do know that cold currents tend to prevent precipitation, I consider myself justified in asking you to put faith in my theory, and my critics may also see their way to let me down lightly. Mr. A. Walter, of the Royal Alfred Observatory (Mauritius), in a paper read before the members of the Meteorological Society of that island, on the 6th July, 1898, said that their winter rains depend probably very much more directly on the temperature gradient over the South Indian Ocean than on any barometric conditions. The snowfall in both hemispheres may not be the sole arresting agency of rain-bearing currents. May not the variation of the meteorological elements of Africa, Arabia, and the numerous islands scattered over the Indian Ocean, be responsible for the sapping of rain-bearing vapour on which Western India so much depends for its rainfall at the regular season? It is an undoubted fact that vast atmospheric changes have taken place in these regions within a comparatively short period, and this disturbance of the regularity of monsoon rainfalls is not exceptional. For instance, the storm field of the South Indian Ocean has undoubtedly advanced westwards. A decade ago cyclones were unknown in the Mozambique Channel; now they are of annual occurrence. May not the unknown agency that has thus caused cyclones now to be regular yearly visitants in a region where they were formerly never felt be the same as is causing the cessation of the monsoon rains in India? That weather authorities in India place much reliance on the meteorological conditions prevailing in the Arabian Sea before the burst of the monsoon is evidenced by the attention paid to the reports of eastward-bound steamers between Aden and Bombay. The observations of such vessels can merely give a vague impression of general conditions, seeing that they can only report upon barometrical variations and markings in their immediate beaten track and over a very restricted area; whereas a hundred miles on either side of them a very different state of things may prevail. In order to arrive at a more definite forecast of the south-west monsoon a more extended system of regular observations is required, both surface and aeriel, in the southern hemisphere. A step in his direction was made at a meeting of the Meteorological Society of Mauritius in February 1905, when it was proposed by the Honourable O. L. O'Connor, and seconded by myself, that the Mauritius Government be approached for financial assistance to establish the kite system of aeriel observation on the principle adopted by the Weather Bureau of the United States. The Secretary, Mr. T. F. Claxton, F.R.A.S., promised to lay the subject before Government. The matter, however, is unfortunately still in abeyance if not entirely forgotten. May I be permitted to suggest to Members of this Society, and particularly to the Indian Section, that they should study the subject, and if it be considered of sufficient importance, that they should bring their influence to bear on the Indian Government, the Colonial Office, and the administration of Ceylon and Mauritius, with the view of obtaining their support, financially and otherwise, for the introduction of a proper system of aerial observations by means of kites as above alluded to, at some, if not at all, of the undermentioned places, viz., Keeling, Cocas, Mauritius, Diego Garcia, and Seychelles. Sakotra being almost in the track of the strongest monsoon current a station there would be of much value, but under present conditions this is not to be thought of on such an inhospitable shore. Mauritius and Réunion Island are now connected by cable. Perhaps the French Goverment may be induced to co-operate in this scheme of aerial kite observations and to establish stations at Réunion and at Mayotte in the Mozambique Channel, thus almost completing the circuit. That there are some hitherto unknown agencies disturbing the rain-bearing currents of the south-west monsoon of late years is only too evident. What these agencies are and how they are to be discovered is the task we have before us, and it is only by Government co-operation and assistance leading to more extended and continuous meteorological observations in the southern hemisphere can we hope to arrive at a more intimate acquaintance with these all important agencies.

C. W. BREBNER, F.R.G.S., M.S.A.

Master S.S. *Secunder.*

The writer hopes that the publication of this article may cause others to give some further information on the meteorology of the Indian Ocean, and the agency which prevents the rain-bearing clouds from travelling on to India during the south-west monsoon. Of late years rain has not only been arrested in parts of India, especially the Western Provinces, but the great island of Madagascar, and the lesser ones scattered about the Indian Ocean, Mauritius included, have suffered from a great scarcity of rain.

Mauritius, 27th August, 1907.

OUT-DOOR ADVERTISING IN FRANCE.

The first enactment relating to the subject of out-door advertising in France is a law dated July 28th, 1791, which is still in force, and prescribes that only a Government poster or announcement may be printed on white paper; all others must be on coloured paper —red, blue, yellow, &c. Every poster or other announcement painted, printed, or otherwise delineated upon a wall, building, or upon canvas is subject to a yearly tax. Temporary "affiches" or posters are subject to a stamp tax, according to size. This is attached either in the form of stamped paper, on which the revenue stamp is applied to the sheet before being printed in such way that the stamp is cancelled by the text being printed over it, or it may be attached adhesively afterwards, and cancelled by a rubber stamp provided for that purpose. Before, however, being publicly displayed, each poster is required to be presented in duplicate at the office designated for that purpose, dated and signed either by the person in whose interest it is prepared or by the bill-poster who is charged with posting the same. According to the American Consul-General in Paris, such antecedent declaration must state fully (1) the text of the poster; (2) the name, surname, profession, and domicile of the person in whose interest it is to displayed; (3) the dimensions of the poster; (4) name, surname, and domicile of the bill-poster who is to post it in public; (5) the number of copies to be posted; (6) precise information as to the streets or squares, houses, or other constructions on which the poster is to be displayed, and (7) the length of time during which it is to be kept in view. One copy is filed at the office of registration, the other—signed and stamped by the official in charge—is returned to the applicant. It will be obvious that a system so rigid and elaborate as this gives the authorities of every village and commune in France absolute control of all posters and announcements displayed in public places, and practically suppresses the abuses which prevail in that respect in certain other countries. No one is permitted in France to deface streets and public places with crude, ostentatious announcements of his business or other subject. Bill boards are infrequent in Paris, and are generally built permanently into a wall, where they are taxed according to their superficial area. When a building is in course of construction and board screens are erected to shield the public from dust and other annoyance, such temporary screen will soon be covered with posters of amusements and other matters, but each poster so displayed has been previously submitted to the authorities, a license obtained, and each sheet bears the cancelled revenue stamp, according to its size. The department stores and other large popular retail establishments have permanent places in the stations of the Underground railway, and their coloured posters which are there displayed are in good taste, and often interesting as works of decorative art. The walls of market-houses bear permanent framed bill boards for the display of administrative announcements. Agencies for the sale of theatre, opera, and other amusement tickets are permitted to display coloured announcements of such performances inside their windows as posters, but the promiscuous placarding of patent medicines and drinks, on houses, fences, and dead walls is not permitted in France. There are in Paris various classes of kiosks or street structures which are devoted to advertising or bill posting, for example (1) round towers known as the Colonnes Moris, made of wood, and used mainly for posters of theatres and other places of amusement. This is the oldest form of kiosk in Paris, and comparatively few of them are now in use except on the leading boulevards and avenues. (2) The "Poste de Vigie" or policeman's kiosk. This is a hexagonal kiosk used as as shelter by the policeman whose post is adjacent to the more important cab stands. Its panels of wood or glass are used for the more permanent class of business advertising, which is printed on the glass or posters covered by glass frames. (3) The news-stand kiosks serve as a shelter and depot for dealers in newspapers and magazines whose stock is usually displayed on shelves or tables under a tent or awning set up outside the kiosk. In Paris kiosks of this class are common throughout the city. They are substantially built, and their panels serve for the permanent display of a large variety of advertisements. Electrical signs are permitted and used to some small extent in Paris, but not so generally as in Berlin, London, and some other European cities. For each sign of this class of public advertisement a special permit must be obtained from the prefecture, and the tax thereon is regulated by the size and character of the sign to be displayed.

IMPRISONMENT FOR DEBT.

The Return of the County Courts (Plaints and Sittings) just issued, which gives the returns for every County Court for England and Wales of the total number of plaints, nnd so on, entered in each Court from the 1st January to the 31st December,

1906 (both days inclusive), and of the sittings of the County Courts in England and Wales holden before the Judges of such Courts in 1906, supply some suggestive particulars as to warrants of commitment for the non-payment of debt. Table 12 shows that in recent years the increase has been considerable. In 1897, 307,035 judgment summonses were issued and 189,107 were heard. Of these, 112,096 were followed by warrants and commitments, and 7,727 debtors were actually imprisoned. In 1906, the number of judgment summonses issued amounted to 390,729, and of these 254,103 were heard; 152,759 warrants of commitment were issued, and 11,986 debtors were imprisoned. So that in the ten years the number of persons sent to prison for failing to pay their debts increased by over 50 per cent The difference in the practice of different County Courts is very marked. For example, Circuit 1 (which includes Alnwick, Berwick-on-Tweed, Gateshead, Newcastle-on-Tyne, North Shields, &c.) only issued 276 warrants of commitment, and imprisoned 43 debtors. And Circuit 59 (which covers a considerable portion of Cornwall only) issued 234 warrants of commitment and imprisoned 10 debtors. On the other hand, Circuit 16 (which has jurisdiction in Barnsley, Bridlington, Hull, Scarborough, and the neighbourhood) issued no fewer than 10,796 warrants of commitment and sent 1,002 debtors to jail, the next largest number of warrants of committal being on Circuit 18, and numbering 10,278; but here the debtors imprisoned only numbered 713. This circuit includes Doncaster, Newark, Nottingham, &c. It would seem that most of the debtors arrested for debt serve the period of imprisonment, the debtors who pay after actual imprisonment being few. Take, for example, a jurisdiction largely agricultural, like that of Circuit 52, which includes Calne, Chippenham, Devizes, Westbury, &c.; only two debtors paid whilst in prison; on the other hand, most of those who are arrested pay or are released before reaching prison. Thus, in Circuit 52, 630 debtors were arrested, and of those 587 were released without imprisonment. Even in a district like that covered by Circuit 47, which includes Greenwich, Southwark, and Woolwich, it will be found that out of 920 debtors arrested 583 paid before imprisonment, and on this circuit 248 paid or were released before the expiration of the term of imprisonment. A good many pay after the issue of the warrant but before arrest. For example, in this same Circuit 47, of 2,122 warrants issued, 352 were satisfied before the persons against whom they were issued were arrested. These figures, and others that might be quoted, would seem to show that whatever the true interpretation of the Act of 1869 under which these committals are made, and however much opinion may differ as to the expediency and equity of imprisonment for debt, the power to imprison does unquestionably bring about in a large number of cases the payment of debts that could not be collected until imprisonment was decreed, or enforced.

SMALL HOLDINGS.

The following circular has been sent by the Secretary of the Board of Agriculture and Fisheries to County Councils and County Boroughs in England and Wales :—

Sir,—I am directed by the Board of Agriculture and Fisheries to inform you that the Small Holdings and Allotments Act, 1907, comes into operation on the 1st January, 1908, and that, in view of the very important and extensive powers which it gives to County Councils, the Board would suggest that your Council should consider at any early date what steps should be taken to carry out the provisions of the Act in their county.

There are many matters of detail connected with the Act which are receiving the careful consideration of the Board, and as to these communications will be addressed to you from time to time, but the Board think it desirable to call the attention of your Council at once to the fact that the Act provides that County Councils may themselves take the initiative in preparing a draft scheme or schemes for the provision of small holdings for their county.

At a later period the Board hope to be in a position to nominate officers to confer with your Council as to the administration of the Act, but they would suggest in the meantime that your Council should at once set on foot preliminary inquiries as to the extent of the demand for small holdings in their county and as to the possibility of satisfying those demands by the acquisition of suitable land either within or without the county. The Board are of opinion that these preliminary enquiries should be as little formal as possible and they think that no better method could be adopted than to invite the individual members of the Council to interest themselves in the matter by making informal inquiries in their respective districts.

It will also be necessary that the provisions of the Act should be made known to the class who are likely to take advantage of it, and in this connection I am to observe that experience has shown that very useful information is often obtained by the insertion in the local newspapers of advertisements, framed in simple language, inviting applications from men who desire land for small holdings, and requesting applicants to forward particulars as to the quantity of land desired, the locality preferred, the extent of their experience in agriculture and the amount of their capital. With this information in their possession your Council would be in a position to consider the steps to be taken to satisfy the demand so soon as the Act comes into operation.

I am further directed to call the attention of your Council to the fact that the small holdings provided by County Councils under the Act of 1892 have in no case resulted in any charge being placed on the rates of the county, and that where small holdings are provided under the Act of this year the possibility of any such charge arising has been very considerably diminished. Under Section 17 of the Act the Board are authorised, subject to regulations to be

made hereafter by the Board with the approval of the Treasury, to repay to County Councils the whole or any part of the expenses incurred by a Council in relation to the acquisition of land for the purposes of small holdings (other than the purchase money, or any compensation, or rent payable in respect of the land), and in pursuance of Section 14 of the Act, the term for the repayment of loans for the purchase of land may be extended to 80 years, and County Councils will be able to borrow from the Public Works Loans Commissioners on favourable terms. In addition, in cases in which the carrying out of a scheme under the new Act, has resulted or is likely to result in a loss, one-half of that loss will be borne by the Exchequer subject to certain conditions which will be set out in a Treasury Minute to be subsequently issued.

I am to add that the expression "County Council" in the Act of 1892 and in the new Act includes the Council of a County Borough.

Copies of the new Act are now obtainable, either directly or through any bookseller, from Messrs. Wyman and Sons, Ltd., Fetter-lane, London, E.C.

(Signed) T. H. ELLIOTT, *Secretary*.

SWISS STRAW GOODS INDUSTRY.

The canton of Aargau, of which Aarau is the capital, is the centre of the straw and imitation straw goods industry of Central Europe. The people of this canton have for many generations been interested in the industry, chiefly because the labour of the peasants has been obtained very cheaply, and they could profitably produce the articles of real straw, on which the proportionate cost of the hand labour required (as compared with the cost of the raw material) forms an enormous percentage of the cost of the finished article. In writing of the present straw goods industry, so-called, a large number of imitations of straw must be taken into consideration. In fact, not more than 5 per cent. of all the output consists of real straw. The American Consular-Agent at Aarau says that in a single list of samples of straw goods recently submitted to him, are included the following materials, which represent articles shipped in the form of finished hats, braids, or bindings, in dozens of colours and finishes, and sold under the generic name of "straw goods:"—Sample 1 consists of wood chip and silk woven together; No. 2, wood chip and ramie; No. 3, "straw" braids of pure silk; No. 4 real horsehair made up with straw and cotton; No. 5, real silk and straw; No. 6, artificial silk and straw; No. 7, silk and ramie; No. 8, ramie; No. 9, cotton; No. 10, wood chip; No. 11, Jedda, or chow-chow; No. 12, woven fancy straw; Nos. 13 and 14, fancy articles made by peasants. The straw used in the manufacture of real braids is usually rye straw, and long of joint. Each peasant, as a rule, grows his own straw, and as soon as his summer farming is over, and his crops gathered in, he and his entire family set to work to split and arrange the straw in the various widths required by the manufacturers; and then the lengths of straw are knotted together, and the resulting thread is made into large hanks, 18 inches long, and tied in bundles ready to be sent to the manufacturers. It is often a matter of surprise that the Swiss can produce articles requiring so much arduous labour at such very low prices. To understand the question it is necessary to study, to a certain extent, the sociological side of the peasant life. Of course, during the summer their work is largely in the fields, but the moment the crops are harvested, and the wood cut and stored for the winter, the entire peasant family engages in indoor work, such as weaving or knitting on the hand looms, which are always lent to the peasant by the large manufacturers of knitted and straw goods. The Consular Agent says that he knows personally of one family of peasants, and this is not an exceptional case, but is typical of probably 75 per cent. of these peasant families, who work during the six winter months of the year at three looms weaving narrow silk and cotton tapes. This family consists of four persons who are grown up, and seven children, whose labour is available out of school hours, and every winter for several years two of the looms have never stopped day or night, except for oiling or the introduction of new raw material. The third loom is run only during the day time by the younger children when home from school. These peasants are industrious and sober people, and are satisfied with a daily profit on the work of the entire eleven members of the family of from four shillings to five shillings and sixpence per day on the whole of their output for six months of winter. This is characteristic of the labour of the Swiss, and especially of the unskilled labour, which produces the straw and imitation straw braids enabling the Swiss manufacturers to ship even to the United States, in spite of American duties, in competition with American workmen. After straw itself silk and imitation silk materials are the products which would be considered of the greatest importance, used in the straw goods industry. Indeed, except for the use of its name, straw plays an exceedingly small rôle in the industry as the following percentages of the manufactured products sold will show. Naturally, these are only approximate, but generally speaking correct. On an output of 100 per cent. in value, the result is as follows:—Tussah silk, 30 per cent.; real China and Japanese mulberry silk, 10 per cent.; artificial horsehair, 15 per cent.; cotton, 10 per cent.; straw, 5 per cent.; ramie, 20 per cent.; and miscellaneous fibres and horsehair, 10 per cent. The real Chinese and Japanese silks made by the worms fed on mulberry and similar leaves, are much too expensive to be used very largely in the industry, but a very large amount of Tussah silk obtained, largely in Manchuria, from worms fed on oak leaves, is annually consumed in Switzerland. Naturally it takes the dye very well, and is fairly light and durable. It is woven into threads of various thicknesses, and again these threads

are made into narrow ribbon-like braids, which are dyed and finished as required. Imitation horsehair is a cellulose product, and is furnished to the manufacturers in the form of thick threads of every imaginable colour, by a German manufacturing trust, with headquarters at Frankfort. This thread is finished and made into braids in the same way as the real silk or real horsehair is prepared. Horsehair is now only used for white or black braids, as it does not take the dye so well as the imitation. It is said that the trust could sell the imitation produced for one half the price now obtained for it, and make a good profit, but at the present price it is only about 60 per cent. of the cost of the real horsehair, and as they control practically the entire output, they keep the price up. Wood chip or wood shavings are used in Switzerland to a certain extent, but it is in Japan that they play really an important part in imitation straw goods. Certain kinds of pine and oak are largely used, the shavings being made with, or across the grain, according to the class of wood used. The finished product is light in weight and fairly durable, but it lacks the qualities of taking the dye satisfactorily, and is generally used only in its natural straw colour. Cotton and hemp are also used in increasing quantities each year, but do not play an important part as yet in the Swiss industry. Certain other plant fibres are used, and even the barks of some trees are required for special purposes. A material known as "Bois de Bohème" is largely used in Italy for certain cheap straw hats. Jedda fibre is a material which would be very largely used if the price of the raw material were not so high. It is part of a plant somewhat resembling an onion, and comes from the island of Réunion. It is a most durable, extremely light, strawlike material, and takes dye as perfectly as silk. The price varies very much from year to year, owing to the uncertainty as to the quantity which the natives will offer for sale. It has been sold as high as 18s. 6d. per pound, and at present it is as low as 2s. 4d. per pound. Jedda fibre is generally known in the trade as "chow-chow." Ramie, of which the importance to the straw goods industry is increasing enormously each year, is a flax-like fibre, obtained from the leaves of the plant of that name, grown largely in India and Manchuria. The cost of the raw material alone prevents its general use by the trade. The large leaves of the plant, resembling somewhat tobacco leaves, are steeped in water, and then by hand the tough veins of the leaf are withdrawn and twisted together, and the whole is "carded," if one may use the term, and prepared somewhat as hemp is prepared, and is furnished to the straw manufacturer in balls some nine inches in diameter, resembling raw cotton drawn out into long strands or ropes. These soft ropes of ramie are passed through hot gelatine baths, and on leaving the bath each thread is passed between two rollers and subjected to immense pressure, the result being a ribbon of the thickness of straw, and about an inch wide. This ribbon is passed through drying chambers, and is finally ready for dyeing or for being cut into the widths required for braiding, &c. Ramie takes dye more satisfactorily, and it is believed that it will gradually replace nearly all other similar materials used in the trade. After the finished dyed threads or bands of straw, or any of the above products, varying all the way from one-sixty-fourth to one inch and a half in width (the latter being obtained by fastening together the narrow bands), have passed through the different processes, they may be passed through various machines to give them a certain surface finish, as, for example, a stippled effect, or a lined surface, or rough, or smooth, or puckered finish.

WINTER-ROT OF POTATOES.

The fungus (*Nectria solani*, Pers.) is one of the commonest diseases of the potato. It attacks stored potatoes, and is always present to some extent, but usually only reaches the proportion of an epidemic during hot, dry seasons, which favour the rapid development and spread of the fungus. The tubers only are attacked, and inoculation, by spores present in the soil, takes place when the tubers are young; but, as a rule, the disease is not obvious when the tubers are lifted, although the mycelium of the fungus is present in the tissues. The further extension of the disease depends entirely on circumstances. If the potatoes are kept dry, and exposed to the air, no further development takes place. On the other hand, if they are stored or placed in heaps so that air is practically excluded, and more especially if stored before being perfectly dry, sweating takes place, the temperature is raised, and within a few weeks the mycelium present in the tubers commences growth.

Description and Life History.

The first external indication of disease is the gradual depression and shrivelling of a portion of the surface of the tuber; these sunken portions are soon covered more or less with white patches of the fungus, bearing myriads of spores, which are quickly distributed by mites and other minute creatures.

At a later stage the white tufts change to a pale pink colour, and produce a second crop of spores, which in like manner are distributed through the heap of potatoes by mites, &c. By such means, the disease quickly spreads, and, aided by bacteria, the tubers are soon reduced to a soft, fœtid mass, the skins alone remaining intact.

During the following season, the most perfect stage of the fungus, in the form of minute crimson-red points, develops on the skin of diseased tubers. The spores of this stage germinate in the soil, and infect future crops.

Prevention and Remedy.

1.—The best preventive against an attack of winter-rot, is to make certain that the potatoes are well dried before storing. Powdered sulphur, if sprinkled over the tubers at the rate of 2 lbs. to the

ton, will destroy the fungus, and also hold in check mites, woodlice, &c., which, by their movements, convey the spores from one potato to another. "Pits" or "clamps" should always be well ventilated.

2.—Land that has produced a diseased crop will certainly be infected, and potatoes should not be planted in it again for some years. Kainit, or lime, may be applied to infected land. Both destroy the fungus. The former is the more effective, and when land is infected, this manure should be used in preference to sulphate or muriate of potash; but the quantity should not exceed 5-6 cwt. per acre, or the quality of the potatoes may be injured. Kainit may be applied in the drills before planting; but in this case, where it is required both as a manure and a fungicide, it would probably be better to apply it as a top-dressing before the horse-hoe is used for the last time.

If the land needs potash, and especially if the potato crop is to be followed by a crop likely to be benefited by potash, as *e.g.*, barley or mangolds, a dressing of kainit may be applied to the infected land as soon as the potatoes have been lifted. If potash is not required, and if the land is likely to be benefited by lime, then it would be desirable to dress the affected field with from 1 to 3 tons of lime per acre.—*Leaflet of the Board of Agriculture.*

CONDITIONS OF SCIENCE WORK IN SECONDARY SCHOOLS.*

In a paper on the "Internal Economy of School Science," read before the Public School Science Masters' Association, in January, 1907, figures were presented relating to conditions of science work in thirty-six public schools. More recently similar data have been obtained from about the same number of secondary schools, working in conformity with Board of Education methods.

In both cases information was asked for on the following points:—Number of boys taking science in (1) general course, (2) special course; average number in class; number of hours per week for (1) general course, (2) special course; number of science masters; number of laboratory assistants; approximate annual expenditure for science; and answers to the following questions:—Do you consider your present arrangements to be adequate in respect of—(1) laboratory accommodation, (2) laboratory equipment, (3) staff, (4) laboratory assistants?

The average results may here be given:—

Public Schools.—In twenty-nine schools 60 per cent. of the boys take science: in twenty-three of these the average percentage of boys in the general course is ninety-five, the remainder being specialists. The number in class for twenty-seven schools is 21·5 in the general and fourteen in the special course. The time for the general course is four hours a week. usually divided between chemistry and physics, and for the special course twelve hours. In eighteen schools the annual expenditure per boy was about £1. Chemistry costs more than physics for maintenance. In twenty-three schools there is a science master for every seventy-six boys, and a laboratory assistant to every 147 boys. Sixty-five per cent. of the correspondents were satisfied with their laboratory accommodation, 71 per cent. with equipment, 77 per cent. with the number of the staff, and only 58 per cent. with laboratory assistants.

Secondary Day Schools.—All boys above twelve years of age take science. The percentage of boys in the general course, lasting four years, is 94, in the special course 6. The average number in class in the general course is 22·6, in special course 8 or 9. The number of hours for science in general course is rather over four a week, and in special course from eight to fifteen. The work is usually divided between chemistry and physics; very little biology is taught. The annual expenditure per boy for apparatus and chemicals is 8s. 6d., or 2s. for one hour of science a week. The average number of boy-hours a week for one science master is about 310. There is one laboratory assistant to 218 boys. Ninety per cent. of the correspondents are satisfied with their staff, 77 per cent. with laboratory accommodation, 80 per cent. with laboratory equipment, and 50 per cent. with laboratory assistants.

It will be seen that the ratio of specialists to boys in a general course is roughly the same in the two classes of schools. In the matter of expenditure the day schools are markedly inferior to public schools. In both there are too few laboratory assistants. The consequences of this misguided economy are that the time of the science master is wasted in drudgery which could be performed less expensively by an assistant, and opportunity for preparation of experiments is lacking.

In answer to the question, "What do you consider to be the maximum size of a laboratory division for successful work?" the average reply from thirty schools was:—Twenty boys in the lower classes, twelve in the higher. It need not be said that these figures still represent only a pious aspiration in many

Another question addressed to the same schools related to the advisability of teaching experimental mechanics as part of the science course. The answers showed a strong feeling of the value, and even necessity, of such a course as a preliminary to all advanced work in physics.

It is to be hoped that this report, fragmentary as it is, may be of some use to educationists and those interested in the supply of secondary education, as indicating the present conditions under which science work is prosecuted in public schools and the better class of secondary day schools.

* Abstract of a paper by R. E. Thwaites, M.A., Wyggeston School, Leicester, read before Section L of the British Association, at Leicester.

DAY TRADE SCHOOLS FOR GIRLS.*

The experiment of day trade schools for girls is still in its infancy in this country, but the promising infant has a great future before it. The standard of wages and conditions of work of women in industry is even lower than that of men. This is due to the fact of woman's double work-wage earning in factory or workshop and the responsibilities of home. The former is apt to be looked upon as temporary and comparatively unimportant, whereas men look upon their trade as their life work. This tendency is disastrous to the 4,000,000 women wage-earners of the country.

To raise the conditions the training for industry must be taken more seriously. At present there are few opportunities for such training. Evening classes are comparatively valueless after girls have worked at trade all day. The Women's Industrial Council has pressed upon the London County Council the need for day trade schools for girls. In October, 1904, the London County Council started the first of these — that for waistcoat making — at the Borough Polytechnic. Now there are, in addition, schools for dressmaking and upholstery at this polytechnic. Also there are classes for ready-made clothing and upholstery at Shoreditch Technical Institute; for dressmaking at Paddington and Woolwich; and for dressmaking, corset-making, and ladies' tailoring at Morley College — to be moved in the autumn to special premises in Westminster, where classes for laundry work are also planned. The broad lines of instruction are the same in each.

Altogether 280 girls are now receiving instruction, and this number will be increased in the autumn. The pupils attend after leaving elementary schools, most of them having scholarships with maintenance grants, and the course is about two years in length; six half-days a week are devoted to trade teaching; four half-days to general instruction, including art work, book-keeping, writing of business letters, and so forth, in close connection with the trade work. The trade teachers are in each case women who have come straight from good positions in the workroom, and who are closely in touch with trade methods. Each class also has an advisory committee of trade experts, employers, foremen, and others, who visit regularly, and give most helpful criticisms and suggestions important to gain the confidence of the trade. Mrs. Oakeshott, the L.C.C. organiser, gains knowledge of conditions in workshops and factories, and helps schools to keep up-to-date.

The girls begin with easy exercises, and soon proceed to more and more varied and elaborate work, instead of beginning, as in the workroom, with running errands and being kept at drudgery tasks to suit the convenience of older workers. The fundamental difference is that in the school the pupils' development is the first consideration; in the workroom, the customers' convenience. The youngest or slowest pupil has the special attention of the trade teacher and the expert advisers, and the use of good materials to practise on, even at the risk of spoiling them. They are also taken to see the best shops, museums of art work, and so on. Another especial advantage is that the hours are short, and the pupils do not get the backache, anæmia, and general weariness which fall to the lot of the girl of fourteen who goes straight from school to work ten and a half hours, or even more, daily in the season.

It is remarkable to see how the girls respond to this teaching. Girls of thirteen and fourteen manipulate blouses and evening dresses in best West-end style; make waistcoats which evoke the enthusiasm of their teacher, who herself "sees something fresh to admire in her trade every day;" and design at their art lessons ornamentations and traceries for embroidery which are tasteful and graceful. The girls are at first made to do the work thoroughly and gracefully, without being hurried; but during the second year they are gradually speeded up and made to work to time. We have not yet much knowledge of what the girls can do when they go out into the trade, but so far as we have any, amongst the Borough scholars, it is encouraging.

It is hoped that the girls now being trained will be equipped by their thorough grounding and insight into all branches of the trade and their higher level of general knowledge and intelligence to rise to the best positions in the trade. If the numbers are increased, and the operations widened, the level of the average worker will be raised, and every girl will be given a chance of being a good all-round hand, taking pride and pleasure in her work; whilst the union in the school of the art and science teaching with the practical details of industry foreshadows a gradual revolution in our trade methods which will raise our industries to a perfection hitherto only pictured by dreamers and idealists.

* Abstract of paper read by Mrs. J. Ramsay Macdonald before Section L of the British Association, at Leicester.

WOOD-PULP INDUSTRY OF NORWAY.

The Board of Trade Journal contains some particulars of this industry taken from a report by H.M. Consul at Christiania (Mr. F. E. Drummond-Hay):—

During the last forty years the quantity of paper consumed has increased so rapidly that the wood-pulp industry has developed in a remarkable way. In Norway it has made wonderful progress, and for some time past Norwegian wood-pulp has held a prominent place in the world's market. A large proportion of the pulp produced in Norway is consumed in the country itself, the manufacture of paper having also made great progress. The export of Norwegian paper in 1906 amounted to 97,143 metric tons, having a value of 16,353,200 kroner (£908,511).

The following table shows the amount of wood-pulp exported from Norway during the years 1902-6:—

	Metric Tons.	Kroner.
1902	447,470	24,736,800
1903	447,744	23,876,600
1904	445,260	24 290,600
1905	442,325	27,620,400
1906	505,627	31,982,400

Of the 505,627 tons of wood-pulp exported during 1906, 362,228 tons was moist mechanical, and 122,923 tons dry chemical.

Sweden, Finland, and Canada are Norway's most serious competitors. The export of wood-pulp from Sweden in 1906 was 414,811 tons, while that of Finland amounted to 56,181 tons.

The prices of wood-pulp have declined considerably since the industry was started. For example, the moist mechanical pulp, which in 1867, 1870, and part of 1874, realised 150 kroner per ton, in 1891 fetched only 29 kroner, a price which left no profit to the manufacturer. The prices of the different kinds of wood-pulp during August, 1907, f.o.b. at Norwegian ports, were as near as possible as follows :—

Dry mechanical wood-pulp, about 95 kroner per ton.
Moist ,, ,, ,, 50 ,, ,,
Dry chemical ,, ,, 145 ,, ,,

The first Norwegian wood-pulp factory was established in 1868. There are now 72 factories, of which 53 are for mechanical wood-pulp and 19 for chemical wood-pulp. Sufficient motive power is furnished by Norway's natural waterfalls; the machinery used in the factories is almost entirely of Norwegian manufacture. A large quantity of Norwegian sulphur pyrites is used in the manufacture of chemical wood-pulp.

About 21 per cent. of the area of Norway is covered with forests. It is feared, however, that in course of time the pulp factories will exhaust the forests, owing to the very small dimensions of wood required in the chemical would-pulp mills. Every year the State plants at least 1½ million trees in the public forests, in addition to which a large number are planted by private owners.

THE INEBRIATES' ACT.

In the report required by Statute concerning institutions certified and licensed under the Inebriates' Act just issued, Mr. Branthwaite refers to the financial reasons for the committal of inebriates to reformatories. Every year's experience, he says, adds its quota of evidence in support of the necessity for the existence of special institutions for the control and treatment of inebriates. In his opinion the cumulative evidence points to three different conclusions :—

(1.) That all habitual drunkards who render themselves liable to be dealt with under the Inebriates' Act of 1898 have become temporarily or permanently diseased, and have passed beyond the limit of responsibility.

(2.) That any attempt to frighten such persons into sobriety by repeated fine or imprisonment has proved useless, and

(3.) That some more satisfactory method is urgently needed to afford the victim a real chance of recovery, or if recovery is passed hope, then to save society from the malicious, criminal, or indecent results of his drunken habits.

In Mr. Branthwaite's opinion the only possible remedy is the substitution of long continued reformatory treatment for the prison methods which still largely obtain. Hitherto more attention has been paid to the humane and scientific aspects of the problem than to the economic. Mr. Branthwaite now puts into concrete form some of the arguments which lead to the conclusion that economic advantages accrue from the curative detention of reformable persons, who if not yet a continuous charge upon public funds must become so if allowed to continue their progress towards hopeless degradation.

If an habitual drunkard is to be reformed, it needs some very energetic measures to prevent him or her from being a regular charge upon public funds for the remainder of life. The only hope for such a case consists in early and long-continued treatment. If the case is taken in hand early, whilst still reformable, the country has to face three years of detention as the only means of avoiding expense throughout the life of the inebriate. If the cost of reformatory detention is brought down to a figure which compares approximately with the cost of the inebriate under conditions of intermediate freedom and prison, then the economist loses practically nothing by imposing reformatory detention during these few years, and gains by standing a reasonable chance of converting a wastrel into a wage earner. Mr. Branthwaite contends that so far as comparatively irreformable drunkards are concerned, reasonable expenditure upon continuous detention is still more justifiable.

"Every case of this character has already become a heavy burden upon public funds, and will probably remain so long as life lasts. In regard to these cases, continuous detention merely uses money (now spent fruitlessly) in a manner more likely to result in protection to the community and possible benefit to the drunkard. As at present spent the money benefits the community but little, and the inebriate not at all."

Mr. Branthwaite gives the prison history of a case sent to a reformatory, the case of a female, whose first conviction was in January, 1881. When she was fifteen years and nine months old she was convicted of being drunk and disorderly. Since then she has been convicted 458 times, or rather had been at the date when his list was made up. There is not a single year from 1881 onwards in which convictions are not recorded against her. Drunk and disorderly, disorderly and obscene, assault, felony, wilful damage, attempted theft, begging. These are the charges upon which again and again in each year she has been found guilty. The record is incomplete because the woman's wanderings have made it impossible to compile a complete history.

"Every scheduled item in her history," says Mr. Branthwaite, "means expense, beginning with main-

tenance and police cells, and the occasional services of police surgeons when arrested in a drunken and comatose condition. Then follows the cost of her maintenance in prison during a great part of each year. The cost of every hearing at the Police Court, committal for trial at Assizes or Sessions, and the subsequent expense of such trial, Court charges for entering recognizances and returning convictions, witnesses fees, cost of summonses and the preparation of warrants of committal to prison, her carriage backwards and forwards (with escort from Court to prison) and her expenses back from prison after the termination of each sentence to the town to which she belongs. There are other charges which she imposes upon the tax and rate payer; and, in addition to this, chronic and apparently irreformable drunkards reproduce their like, and by their influence and example manufacture others of their kind. They become insane, and add to the lunacy bill, or they become diseased, decrepit, and prematurely aged, to be a burden upon the charges of the Poor-law."

Continuous reformatory detention saves the majority of these expenses. During the detention the community escapes danger and annoyance, and the drunkard has a chance of recovery, which the short sentence prison method does not give. The conclusion seems irresistible, that reformatory detention at reasonable cost is the most logical and economical method of dealing with the comparative irreformable, provided recommittal is frequently resorted to in order that detention may be made as continuous as the law permits.

COPPER MIRRORS.*

The importance from the point of view of the health of the workpeople of obtaining a substitute for the tin amalgam used in the manufacture of mirrors has led many chemists to study the conditions under which metals are deposited from aqueous solution. These investigations have, however, usually had for their object the preparation of a liquid which would deposit a uniform and coherent layer of silver over a a large glass surface at the ordinary temperature. Liebig was the first to solve this problem satisfactorily, and his method in which milk sugar is the reducing agent was formerly extensively used.

Other metals are not so easily deposited, and copper, which from its close relationship with silver one would expect to behave similarly, has never been observed to be laid upon glass. Although copper mirrors have never been obtained by deposition of the metal from an aqueous solution, Faraday † about the time when silver mirrors were attracting much attention made the interesting observation that a mirror-like deposit could be obtained by dissolving a little oxide of copper in olive oil and heating plates of glass in a bath of this liquid up to the temperature at which the oil decomposes. The mirrors, however, obtained by Faraday's method, if of any size, are liable to be stained or discoloured in patches by decomposition products of the oil, and they are, moreover, generally lacking in brilliancy. Further, as the deposition of the metal only takes place when the oil decomposes, the process is excessively disagreeable to carry out; and since the oil is spoiled it is also somewhat costly.

In the course of an investigation on the oxidation of aromatic hydrazines, the author made the observation that when solutions of cupric oxide are reduced by these compounds the metal is deposited upon the glass in the form of a brilliant coherent film if clear vessels are used.

The mirrors obtained by this method are very beautiful, as they show the lustrous red colour of burnished copper, and are as perfect in reflecting surface and as uniform as the similar mirrrors obtained by the deposition of silver.

It seems probable that this method of depositing copper upon glass could receive important application in the production of objects of art.

INDIA'S INSECT PESTS.

The tea planters in India have great trouble on account of insects which attack the tea plants. The bark-eating borer, the sandwich caterpillar, the mosquito, and the white ants all attack the plants and do immense damage. The white ant, according to the American Consul-General at Calcutta, is one of the most destructive of all the insect pests of India, there is no wood that resists its attack except sandal-wood. It delights in reducing white pine or white wood to powder. The ant cannot work in the light, it must get at the wood from a dark recess and work within a shell. It will, in some mysterious way, get into a veneered picture frame, or one with a thick coating of lacquer, and in a short time, only the veneering or lacquer remains, while the white wood body of the frame is found to be entirely reduced to powder of the finest sort, and but little of the powder remains, the ant having consumed the bulk of the wood. Its method of destuction is by emitting a kind of acid, which deteriorates the wood. The Consul-General says that an acquaintance of his was absent from his home for a few months. He covered his furniture and prepared thoroughly, as he thought, against the ravages of insects. On his return he sat down in a chair that had been carefully covered, and it crushed down beneath his weight as if it had been made of cardboard. Upon examination it was found that the white wood body of the chair had been eaten out by white ants, leaving only the veneering and gold-leaf covering. The other chairs of the set were examined and all were found to be in the same condition. The furniture appeared intact, but the moment it was touched it crumbled into dust. The

ants will get into joists and eat away the centre, leaving only shell. Several long joists thus eaten out have been replaced in the American Consulate by iron ones. The white ant is the curse of the country, and there seems no way of exterminating it or of preventing it from getting into mischief. This is one reason why the natives build their houses of mud even where timber is plentiful. The finest houses in the large towns and cities are constructed in a way as far as possible to cover, or imbed woodwork in cement. Especially the ends of wood structural work are thickly covered with cement to prevent the boring of white ants. Most of the floors, as well as walls and ceilings are covered with cement. The white ant is a source of considerable anxiety to tea planters, and the entomological station of the Indian Tea Association is investigating the matter with a view, if possible, of protecting tea plants from this and other pests, including the green fly, which of late has been giving a great deal of trouble.

ADMIRALTY CHARTS.

The following is the official list of charts issued by the Hydrographic Department, Admiralty, in August, 1907:—

New Charts.—No. 2881—Gulf of Mexico:—Key west harbour and approaches; plans of Key west harbour and north-west channel bar. 1739—China:—Chu-Kiang or Canton river, sheet V.; Whampoa channel and Changshan island to Canton. 3649—Tasmania, north coast:—Entrance to river Tamar. 2799—South America, west coast:—Plans on the coast of Ecuador and Peru. Plan added:—Port Bayovar. 1115—China, north-east coast:—Yang tse kiang, sheet V.; Yo-chau-fu to Kwei-chau-fu Plans added:—Sketch of Tching Tan; sketch of Kung Ling Tan. 1268—Plans in the Kuril islands. Plans added:—Shari road, Rausu road. New plan:—Anama harbour.

Charts that have received additions or corrections too large to be conveniently inserted by hand, and in most cases other than those referred to in the Admiralty Notices to Mariners.

1188—The World:—Coal and telegraph chart. 1481—Scotland, east coast:—River Tay. 2495—Ireland, south coast:—Kenmare river, &c. 3158—Norway:—Nevlunghavn to Torbiornskier, &c. 3159—Norway:—Torbiornskier to Jæløen. 881—Norway:—Aakre to Hisken, &c. 2309—Norway, sheet VII.—Leka to Donnæsö. 2628—Malta island, south-east portion. 644—Africa, east coast:—Delagoa bay (*Lorenzo Marques*). 216a—Bay of Bengal, Mergui archipelago:—Lord Loughborough island to Mergui. 3612—China, south coast:—Port Shelter and Rocky harbour. 1760—China, east coast:—The Brothers to Ockseu islands, &c. 2513—New Zealand:—Napier port and harbour.

These charts are issued by Mr. J. D. Potter, 145, Minories.

HOME INDUSTRIES.

The Hop Crop.—The brilliant weather of September greatly improved the hop crop outlook. Estimates of the total crop vary considerably, but it would seem safe to say that it will exceed 400,000 cwts. The acreage is 44,938, and given 9 cwt. to the acre there would be a total yield of 404,442 cwts., or no less than 158,442 cwt. in excess of last year's yield. Owing to the lack of sunshine in August the hops are small but they are of good brewing quality, and of fine flavour. The average yearly consumption of hops in the United Kingdom is a little over 600,000 cwts.. but considerable stocks are held by brewers, and the crops in the chief hop-growing districts on the continent are exceptionally heavy, so that brewers have no cause for anxiety as to a possible shortage of hops. Unfortunately for the home grower prices are not on a remunerative basis. In a recent circular Messrs. Mangar and Hanley put the position accurately when they say, "Compared with thirty years ago more hops are now obtained per acre—science in farming and skill in the handling producing larger averages—but notwithstanding these advantages the commercial results point to a very serious loss of capital, and the existing state of the trade unhappily indicates a further decrease." The shrinkage in the area of culivation shows small sign of slackening. In 1905 the area under hops was 48,968 acres, last year 46,722 acres, this year only 44,938. Last year the reduction was over 4 per cent. on the 1905 acreage, and this year it is over 3 per cent. on 1906. In the last ten years the reduction has been nearly 10 per cent. It is not easy, or perhaps possible, to suggest a practicable remedy for this regrettable contraction. Many causes have combined to bring it about, and these causes are still operative. It is a noticeable fact that something like three-fifths of the breweries of the Uuited Kingdom refuse to use foreign hops, and depend wholly upon the home growth, but fewer hops are used in proportion to the brewers output than formerly. It has been suggested that a conference of the trade be held to consider whether anything can be done to encourage the hop growers, and whilst something might come of it such a conference could do no harm. It is certain that the acreage under hop cultivation will continue to decrease unless the average of prices can be raised, and the present comparatively high price of wheat, and the prospect of a further considerable rise, will quicken the inclination to grub up. It is not to the interest of the brewers that this grubbing process should continue. Some at least of the money spent by the brewer at home for hops comes back into his coffers, but none of the money he sends abroad for foreign hops returns to him. It is to his interest to see the home cultivation maintained and increased, but as things are further shrinkage seems certain.

Coal Miners' Profits. — Much is being said just now about the excessive profits that are being made by coalowners, and it may be interesting, therefore,

to refer to an analysis of working costs made by Sir Christopher Furness, and submitted by him last week to a meeting of colliery shareholders. Sir Christopher Furness submitted his analysis to Messrs. Holmes, Spencer and Co., who, it may be mentioned, are the chartered accountants employed by the miners in the quarterly assessments of prices on which wages are based, who endorses it. Reduced to percentages, the analysis shows that for every £100 spent by the company with whose accounts Sir Christopher Furness was dealing, accounts said to represent a fair average of the trade—52·44 per cent. went to labour directly in money; 5·66 for rates, coal and house rent—that is interest on capital spent in building miners' houses; 1·80 per cent. to labour for management at collieries, harbour, head office, &c.; making a total for labour of 59·90 per cent. Materials cost 6·63 per cent.; provender for pit ponies, 1·36 per cent.; shipping charges, 1·55 per cent.; railway dues, 1·24 per cent., which are largely made up of wages, making a total of 10·78 per cent. Then rates and taxes accounted for 1·35 per cent.; coal trade calls, including compensation for accidents, horse depreciation, damaged land, insurance, &c., 2·72 per cent.; redemption of manor arable royalty, 1·04 per cent.; royalties, rent, way leaves, 4·21 per cent.; Reserve Funds for depreciation, 9·49 per cent.; remuneration to capital, 10·51 per cent. If the actual cost of production is taken—that is, money expended in raising coal, exclusive of reserves for depreciation and remuneration of capital—labour receives, according to these figures, 75·87 per cent. Sir Christopher Furness's comment is as follows:—"These figures do not bear out the contention that capital is overpaid. even in a good year such as that to which they relate, and for four years ordinary shareholders received nothing." If this fact is considered, the return on capital is reduced to 6·73 per cent.

Wolfram and Tungsten.—A few years ago wolfram ore could not be sold at £15 a ton, and the world's output was only about 300 tons. But since then there has been a steady growth of demand, and the output last year was about 3,500 tons, whilst the price had risen to £150 a ton. It is found for the most part in Boulder County, Colorado, although some is obtained in Northern Queensland, and a little in Cornwall, where, however, the ore deposits of wolfram, as a rule, are small and irregular. Tungsten of soda is prepared from wolfram, and is used with starch for rendering light fabrics, such as muslin, uninflammable. It is also the chief substance from which tungsten acid is derived, and metallic tungsten is prepared from it. In recent years this has been largely used in Sheffield for hardening high-speed and special tool steels, some of which contain up to 20 per cent. of tungsten. The rareness of the metal, and its high price—metallic tungsten has been selling at £450 a ton—has prevented its being largely used, but large deposits of wolfram are being opened up in Colorado, and a company is being formed in Manchester and Sheffield for working some of these deposits. If larger supplies could be obtained at a lower price, tungsten would be much more extensively used.

The Cotton Crop.—Mr. Hester's annual report on the cotton crop of 1906-7 has just been received. Mr. Hester says that it would have been the largest cotton crop ever grown but for the storms last autumn, which also had a considerable effect on the quality of the cotton. So exceptional was the weather during a part of the season that it appears that the average grade of the crop was low middling to middling, as compared with fully middling for the season before. On this basis, the crop sold at an average price of 10·29 cents. per pound, and Mr. Hester shows that the money value of this last crop is the largest ever received—716,352,265 dols.—although the yield of cotton was not quite equal to that of 1904-5, when the value was only 628,195,359 dols. With regard to the relation of the cotton grown to the commercial crop, Mr. Hester considers it certain that the past season saw a closer marketing than in the case of any of the preceding great crops. He makes the commercial crop, 13,510,980 bales, and the actual growth, 13,630,000 bales, so that the difference is only about 120,000 bales. The average weight of the bales is given as 515·02 lbs., or the heaviest on record, with the exception of the 1904-5 crop, which averaged 515·58 lbs., the inference being that the larger the crop the larger the bale. Mr. Hester gives many interesting statistics relating to consumption, and particularly to the progress made by the Southern mills. During the year there was an increase of 791,065 spindles in the mills, and the "new and not completed mills" which should soon be in operation, will add another 640,978 spindles. The labour difficulty is acute at present, and in Mr. Hester's opinion the South would have used another 200,000 bales of cotton last season if it had been fully manned. Yet the Southern takings were 2,439,108 bales as compared with 2,374,225 the previous season, and 2,163,505 the season before. "This year the facts," says Mr. Hester, "indicate more positively that the trend is clearer than ever in the direction of America eventually consuming her own cotton, to be sold to the world in manufactured form instead of as raw material, and the indications are further that most of this change will be brought about in sections almost immediately adjacent to the cotton fields." Fortunately for Lancashire the time is distant when this will be the case, and before then, it may be hoped, the British Empire will supply a much larger percentage of the British requirements than it does at present.

Wheat.—Not for many years has the British farmer been in such a favourable position as to his wheat as

now. The total wheat crop of the country promises to be considerably larger than the estimates of the summer, and the perfect weather of September has enabled it to be gathered in splendid condition. It is now thought likely that the crop will reach 6,750,000 qrs. as against 7,580,000 qrs. last year. And whilst the yield will be good, prices are much higher and are likely to go a good deal higher. Last year the price of wheat remained steady at from 28s. to 29s. during the first quarter of the year, and then rose slightly but steadily until the end of May when it remained at a little above 30s. until harvest. A fall of about 4s. then occurred, and the market remained at a level of about 26s. for the remainder of the year. Now it is over 38s., and prospective supplies fall very short of requirements. It is believed that the American surplus available for export will be less than last year. The present large exports of white wheat must soon come to an end, and it is doubtful whether any of the spring crop will be available for export beyond a moderate quantity of "durum," or macaroni wheat. The Canadian outlook is even less favourable. The Manitoba crop was sown very late, and had short time to ripen before the frosts came, the extent of which is said to be serious. And the short crops in America are not likely to be counterbalanced by good crops elsewhere. It is estimated that not more than 500,000 quarters per week will be forthcoming from other countries than the United States and Canada, while European countries require at least 1,200,000 quarters for seed. It is from Russia and the Danubian countries that the main supplies in the last three months of the year are usually obtained. Taking the last three years, more than half the total import has been from these countries in those months. Telegrams from Russia published last week spoke of the great prospective exports from that country, but the official estimate of this year's crops shows serious shrinkage. Comparing it with the final returns in 1905-6, in quarters and omitting 000's, the figures are as below:—

	1905. Qrs.	1906. Qrs.	1907. Qrs.
Winter wheat....	27,400	29,722	17,560
Spring wheat....	51,835	38,375	41,325
	79,235	68,097	58,885

So far as Russia is concerned the enhanced prices make up for the deficiency, but that does not help the British consumer. The Australian crop again is by no means assured, and there is no ground for supposing that the supplies from Argentina and India will show any great excess. In Berlin the price of wheat has already reached 50s. per quarter, and much higher quotations seem probable here. In France on the other hand, this year's wheat crop is about 3½ million quarters in excess of the annual consumption, and wheat is 10s. per quarter cheaper than in Germany.

GENERAL NOTES.

Riga Sawn Goods. — The effect of extreme competition is strikingly illustrated in Mr. Consul Woodhouse's report (Cd. 3283—176) on the trade and commerce of Riga for the year 1906, just issued. The great competitor of Riga whitewoods in the markets of the United Kingdom is Canadian spruce, but the demand of the United States for Canadian spruce has lately been very large, and prices have ruled so high that spruce shippers have been obtaining in the United States the equivalent of about £8 10s., £8 15s., c.i.f. London for 3 × 8 and 3 × 7 unsorted. Riga exporters seem to have ignored this fact. They commenced selling on a basis of from £8 to £7 15s., for the above dimensions, and "by their cut-throat" competition with one another, succeeded, by the month of April, in enabling the United Kingdom buyers to purchase from them at £7 6s. 3d. c.i.f., goods which they could not obtain elsewhere—that is, from Canada—under at least £8 10s. to £8 15s. c.i.f. Mr. Wodehouse explains this by saying that the Riga exporters of sawn goods are a badly organised body. They tackle more goods than they can comfortably finance. Their one idea seems to be to turn out as much stuff as they can, and get it shipped off before the winter comes, so as to have less stock to finance over during the closed time of winter. The result is that, through fear of not clearing their production of the summer and autumn before the winter comes, and easing themselves financially by getting their money back, they operate one against the other in making sales, and forcing the foreign markets.

Pastes in Italy.—Mr. Vice-Consul Carmichael directs attention in his report on the trade and commerce of Leghorn (Cd. 3727-3) to the increasing use of Italian pastes. At one time macaronis were a Neapolitan and South Italian article of consumption, and as such they are still regarded by many people not conversant with modern Italian developments. As a matter of fact, pastes are now as popular in the north of Italy (where rice formerly took their place), as in the south, while the improved condition of the agricultural and working classes, enables them to indulge more and more in this nutritious form of food to the exclusion of "polenta" rice and chestnuts. This development suggests to the Vice-Consul the question whether the manufacture of pastes might not profitably be extended to other countries. As food, it is agreeable, wholesome, and very nutritious, and by the expenditure of a few pence in meat for added condiments it can be transformed into a variety of savoury and appetising dishes. Mr. Vice-Consul Carmichael suggests that a general development of the use of freshly-made pastes might do much to solve the food problem among the poorer classes, giving the best possible nourishment at the lowest possible cost.

Journal of the Society of Arts.

No. 2,864. VOL. LV.

FRIDAY, OCTOBER 11, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

EXAMINATIONS.

The programme for 1908 is now ready. The price of the Programme (containing the previous year's papers and the examiners' reports on the work done) is 3d. (post free 4d.) Copies can be had at this price on application to the Secretary, Society of Arts, Adelphi, W.C.

The examinations are now arranged under the following stages:—Stage I.—Elementary; Stage II.—Intermediate; Stage III.—Advanced.

The subjects include:—Book-keeping, Accounting and Banking, Shorthand, Typewriting, Economics, Précis-writing, Commercial Law, Commercial History and Geography, Arithmetic, Handwriting, and Modern Languages.

The Examinations will commence on Monday, April 6, 1908.

In the Advanced and Intermediate Stages First and Second-class Certificates will be granted in each subject.

In the Elementary Stage Certificates will be given in each of the subjects enumerated. These will be of one class only.

Certificates of proficiency will be granted in each grade to Candidates who pass in certain specified subjects during a given period.

In Rudiments of Music Higher and Elementary Certificates will be given; in Harmony Higher, Intermediate, and Elementary Certificates.

A fee of 2s. 6d. will be required by the Society from each Candidate in each subject in the Advanced and Intermediate Stages, and in the Elementary Stage a fee of 2s. for one subject, and 1s. for each additional subject taken up by the same candidate. The fees for Harmony and Rudiments nf Music are the same as for Stages II. and III.

Medals and Prizes are offered in each subject in Stages II. and III. Full particulars will be found in the programme.

Examinations are also held in the Practice of Music, and Vivâ Voce Examinations in French, German, Spanish, Portuguese, and Italian. For information as to these examinations reference should be made to the Programme.

"OWEN JONES" PRIZES FOR INDUSTRIAL DESIGN.

The Council of the Society of Arts hold a sum of £400, the balance of the subscriptions to the Owen Jones Memorial Fund, presented to them by the Memorial Committee, on condition of their spending the interest thereof in prizes to "Students of the Schools of Art who, in annual competition, produce the best designs for Household Furniture, Carpets, Wallpapers, and Hangings, Damasks, Chintzes, &c., regulated by the principles laid down by Owen Jones."

The prizes will be awarded on the results of the annual competition of the Board of Education, South Kensington. Competing designs must be marked, "In competition for the Owen Jones Prizes."

No candidate who has gained one of the above prizes can again take part in the competition.

The next award will be made in 1908, when six prizes are offered for competition, each prize to consist of a bound copy of "The Leading Principles in Composition of Ornament of Every Period," from the Grammar of Ornament, by Owen Jones, and the Society's Bronze Medal.

THE MECHANISM OF THE SOUTH-WEST MONSOON.*

By Sir George Birdwood.

Our terraqueous globe is wrapped in a layer of air about 40 miles high. This air is chiefly a mechanical mixture of nitrogen and oxygen gases, but it is also the recipient of all the volatile matters ever rising from the surface of the globe, and, among others, of the vapour of water in proportionally large quantity. The heat of the sun draws up the watery vapours from the seas and rivers, and so long as it remains in the state of vapour it is invisible; but on cooling it again takes palpable form, and falls to the earth from which it rose. It may be condensed and precipitated either by the greater cold of the higher spaces of the atmosphere into which it has ascended, or through being traversed by a colder current of air, or from its being whirled, with the revolving globe, away from the heat of the sun into the earth's cool shadow, we call the night. The cold of a clear night precipitates it as dew, or as hoar frost, which is frozen dew. A fog is caused by the condensation of the watery vapour in the air that rests directly on cold ground. A cloud is a fog high in the air, and snow is a frozen cloud which, as it congeals, descends. Rain is caused by the gathering together of many clouds, or aerial fogs. The sun cannot dissipate them, and their moisture gradually collects in drops, which fall as rain, Hail is a shower of rain, suddenly frozen as it falls. The heat of the sun also sets the atmosphere in motion, the winds which blow over the face of the earth being caused by the unequal heating of the air. When a fire is lighted, the air it heats ascends the chimney, carrying the smoke with it, and the vacuum caused in the air of the room draws to the hearth the colder outside air through every opening in the doors and windows; and when a city is on fire, so great is the vacuum caused by the upward draught of heated air, that the cooler surrounding air flows in to take its place as a violent wind; and so in accounts of great conflagrations we often read that the terror of the inhabitants was increased by the hurricane which blew at the same time. In such a fire it will be observed that the column of smoke from it does not go up for ever, but as it rises into the cooler air it spreads out on all sides like the branches of a palm, and gradually falls in "blacks" to the earth; and in this way bits of charred wood and paper are often brought back to a fire by the wind caused by it. Within the tropics the sun's rays fall vertically on the air, and its heated particles, constantly rising, form a column ever moving towards the poles. To fill the vacuum thus caused, colder air from the frozen poles rushes down over the surface of the globe towards the equator, and hence result the great polar and equatorial air currents, the direct courses of which between the poles and the equator are bent by the revolution of the earth on its axis, in the northern hemisphere into the North-East and in the southern hemisphere into the South-East "trade winds," or *vents alisées*, called "trade winds," not because they facilitate commerce, but because they hold a certain steady course, trend, or "tread" all round the earth. The air brought by the "trade winds" ascends to a great height in the tropics, and flows back towards the poles, in the northern hemisphere as the South-East "anti-trade," and in the southern as the North-East "anti-trade." The ascending air carries with it an immense volume of watery vapour, and as the air is quite calm on or near the equator, where the trade winds meet, this vapour, as soon as it reaches the upper atmosphere, is at once precipitated in the rains which fall within the tropics nearly all round the year. It is now proved that the Assyrians 3,000 years ago had anticipated Dr. Hunter's theory of the periodicity of sun spots, which implies that they also understood the theory of climate, as expressed in Ecclesiastes i. 6: "The wind goeth towards the south, and turneth about unto the north; it whirleth about continually, and the wind returneth again according to his circuits." Had the world remained, as it probably once was, a waste of waters, the trade winds would have blown over it, and all round the year, uninterruptedly, and the moisture in the air would have fallen on the earth in three continuous belts, one corresponding with the equator, and the others with the calms of Cancer and Capricorn; these calms would indeed have reached to the poles, and darkness covered the face of the deep. But the globe is divided between sea and land, and the land becomes hotter more quickly than the sea, as shown by the "sea breeze," that begins to blow about noonday in the tropics; and cools more quickly, as shown by the dangerous "land wind" which in tropical countries begins about midnight to blow over land toward the sea; and the consequence is that when the sun becomes vertical over any portion of the earth's land surface, it draws the surrounding air to a focus there; and in this way, in every latitude, the great primary winds and rains are broken into secondary, or local winds and rains, producing the differences in nature and season of the climates prevailing over the globe. Thus the manifold climates of the world are caused by the mutual relations of its atmosphere and sea and land; and all the changes of weather, shade and sunshine, heat and cold, calm and tempest, drought and rain, depend upon the movements the atmosphere is thrown into by the sun.

Owing to the excess of land in the northern hemisphere, the constant belt of rain where it exists between the trade winds, instead of corresponding with the equator, lies a little to its north, and the moisture gathered by the South-East trades only falls in rain when it reaches the tropic of Cancer, thus compensating the northern hemisphere for its want of evaporating (sea) surface. Similar modifications and compensations, on a smaller scale, occur in regard to each

* Monsoon = Arabic mausim "season," through the Portuguese monção. This article was originally contributed by Sir George Birdwood to *The Times*, and is reprinted here *en suite* of Mr. Brebner's article in the *Journal* of last week.

of the trades separately as the sun successively passes through the North and South ecliptic. But here we have only to consider "the Rains," or "South-West Monsoon" of Western India. India stretches out into the belt of the North-East trades, and were there undeviating winds the only rain this immense, outspread peninsula would receive would be that which falls from October to April during the North-East "Monsoon." The rain which then falls is not brought by this wind, for as it blows from the high lands of Eastern Asia, it bears with it but little watery vapour, except what it may lap up in the Bay of Bengal. But the great volume of rain falling on India during the North-East Monsoon, or winter rains, is really derived from the evaporation of the ocean about Australia, where during our winter months the sun is shining with all the force of mid-summer. The vapour there drawn up into the higher atmosphere returns in an upper current towards India, where it is precipitated through the lower current blowing from the north-east, and furnishes the North-East Monsoon rains, on which the Indian winter crops depend. If India depended on the North-East Monsoon rains alone, it would indeed be almost as unfortunately circumstanced as the peninsula of Arabia, wedged in between the high lands of Persia and Abyssinia. But observe what actually takes place. At the vernal equinox, March 21, the sun passes from the southern hemisphere to the northern; is first vertical over Bombay about May 15; reaches the highest point of his upward journey, or summer solstice, June 21; descending, is again vertical over Bombay about July 27; and finally, at the autumnal equinox, September 23, having traversed the whole tropic of Cancer, re-enters the tropic of Capricorn, reaches its lowest southern point, or winter solstice, December 23. Between May and July he shines down furiously on the sandy plains of Scinde and Rajputana, and the great grassy plains of Central Asia, from which so vast a column of heated air ascends up through the atmosphere that the draught caused has the power not only to reverse completely the normal direction of the North-East trade, but even to deflect and draw the South-East trade toward India. Thus is the South-West Monsoon brought about. This mighty wind, laden with the moisture gathered from the Indian Ocean, strikes the Malabar Coast and the Concans at nearly right angles, and there, chilled by the cool, green, forest barrier of the Ghats, pours down its condensed vapours on Western India for four months in violent rains, which are ushered in and depart with the most awful thunderstorms; and thus also it is that the temperature of India is lowered during months that otherwise would be so hot as to make the country unendurable. The Deccan slopes eastward, having been upheaved chiefly by the eruption of the Western Ghats, and the superfluous rain which falls on them, that does not flow off in the mountain torrents of the Concans, slowly drains off to the Bay of Bengal in such continental rivers as the Godavery, Cauvery, Pennair and Kistna. But the Ghats do not line the whole coast; they cease about Surat; and there the Sautpura and Vindya mountains condense the clouds borne by the South-West Monsoons, and pour their waters into the Arabian Sea by the flooded Tapti and Nerbudda, the only Deccan rivers flowing westward; while from the Aravalli hills in Rajputana, the Sabarmatti flows south-westward through the fertile plains of Gujerat. The South-West Monsoon reaches to the wide plain of Hindostan, the Punjab, and Scinde; and all round the coasts of India and Southern Asia, within the influence of the great solstitial up-draught from the deserts of Rajputana and Central Asia, we find the phenomenon of summer rains. At the very time, also, that the sun is drawing the vapours of the Indian Ocean towards the Western Ghats, his rays are melting the snows of the Himalaya and Hindu Kush, which flow down to the Arabian Sea and Bay of Bengal, in the perennial streams of the ancient Indus and sacred Ganges.

The mystic Saraswati, which once flowed through Rajputana to the sea, has long ages ago disappeared through the desiccating action of the summer solstice, or "standing still" of the sun over that country between May and July. The evaporating away of this river of Hindu poetry is a proof of how little unphilosophical political agitators take into account the play of natural climatic forces in India. We have traced the course of the sun through Cancer and Capricorn, and it will have been observed that he shines vertically twice as long over his "turning points" as over any other part of his ecliptic course. He appears to stand still over these points, which are hence named the summer and winter solstices; and so it happens that all the lands lying about the 23rd degree north and south of the equator, under these sun stations are desert lands. This is clearly seen in the northern hemisphere, where there is so much land, in the deserts of Rajputana, Scinde, Baluchistan, Persia, Arabia, in the Great Sahara of Africa, and the Tierra Caliente of Mexico. In the southern hemisphere there is very little land along the solstitial line, and what exists is surrounded by the widest oceans; but Central Australia is a desert, and the Kalahari desert stretches across South Africa, and the Pampas through South America. India is, in fact, one of the blast furnaces wherein the winds of the world are evolved, bearing with them everywhere fire and hail, snow and vapours, and the life-giving, purifying oxygen disengaged in ceaseless and immeasurable volumes from the perennially green primeval forests of the tropics. So placed at the very focus of her mightiest operations, man must stoop very humbly to Nature if he would hope to understand her and subdue her to his purposes; and this, through 3,000 years' experience, the patient, religious-minded Hindoo has learned to do; and it is certainly not for the farmers of our mild, equable climate to be too sure of being able to improve on Hindoo husbandry, or to insist too energetically on

the superiority of their own doctrines and methods. The real wonder is that India does not suffer more from agricultural distress and famines, and the reason of its comparative exemption from them lies in the phenomena of the South-West Monsoon. But most precarious, from a merely scientific point of view, is the yearly prospect of the seasons in India between the date of the solstitial hyperthermescence of the Rajputana desert and that of the storm of rain it calls up from the vasty deep. It always comes, but one might every year repeat the question, "Will it come?"—with the prayer, "God help its coming!" Any alteration in the condition of Rajputana by improved irrigation, or extended forest planting, or by an increase of its desert area, might produce incalculable results of the most disastrous character. The destiny of India seems, in fact, to hang in the balance between this desert country and the deep sea. The Hindoos themselves have always been devoutly alive to those solar influences and atmospheric phenomena that so intimately affect their prosperity and happiness as an essentially agricultural people. The gods of the earlier Vedic Hindoos are but the vaguest impersonations of the heat and cold, rain and drought, whose effects on their crops and herds were at once felt; and in the mythography of the later Brahminical Hindoos the first place was still given to Agni or Fire ["ignis"], and to Surya, the "shining" Sun, and to Vayu, the "vague," "vagrant," "vagabond" Wind, or to "domineering" Indra, the "atmospheric" Firmament [dome]. They together were pre-eminently the gods over all the gods of the earlier Brahminical "symmistry," or "college of gods," foreshadowing the Tri-murti or "tri-form" supreme divinity [Brahma, Siva, and Vishnoo] of the finally constituted pantheon of the Puranic Hindoos.

THE FOREIGN TRADE OF INDIA FOR THE YEAR 1906-7.

The grand total of Indian imports and exports combined was 317 crores of rupees in 1906-7, as against 292 crores in the previous year, the growth being one of 8·77 per cent. The increase was more pronounced in the case of imports than exports. Taking the trade by provinces, it is curious to observe that Bombay was the only province where the total value of merchandise received and exported actually showed a decline, the figures having been adversely affected apparently by the competition of Sind, where the value of the exports rose as high as 38 per cent.

IMPORTS.

In the group of articles of food and drink, the most important item is sugar, which represents 52 per cent. of the value of the whole group. The feature of the year was one of low, but fairly constant prices, the large shipments to India counting for a great deal in steadying the markets. On the whole, the imports of sugar very largely exceeded earlier records, both in quantity and value. The shipments of cane sugar exceed those of beet—close on 6 million cwt., as against less than 4 million cwt.—the premier place being occupied by Java, which in 1905-6 had ceded it to Austria-Hungary, a beet country, Mauritius being second. Under the somewhat comprehensive head of provisions, it is interesting to notice that there is a steady increase in the imports of foreign biscuits, and this in spite of the establishment of biscuit factories in India. This seems to indicate the acquisition of a new taste by the natives. As regards salt, there was, as in 1905-6, a small decrease in the quantity imported, this being attributed to the boycott of foreign goods. On the other hand, it is satisfactory to note that the successive reductions of the Indian salt duty have been accompanied by a growth in consumption. Liquors, *i.e.*, malt liquors, spirits and wines, have all declined both in quality and value, a result due, no doubt, to the competition of the breweries and distilleries now in full operation in many parts of the country.

Owing to a shortage in the Ceylon crop and in China shipments, and to a full crop in India, the imports of tea declined 29 per cent. in quantity and 12 per cent. in value.

In the important group of metals and manufacture of metals, interest attaches to the head of enamelled ironware, which now assumes for the second time the premier place, and the value of which during the year has actually increased 41 per cent. This is due partly to the high prices of copper and brass, and the extent to which domestic utensils of those metals have been replaced by German and Austrian ware marks an extraordinary change in immemorial habits throughout many thousands of native houses. Of this trade Germany now does 68 per cent., as against 54 per cent. in 1095-6, while Austria, which was supreme in it till two years ago, has receded from 42 per cent. to 23 per cent. Among minor heads lamp-ware and (to a less extent, of course) sewing machines show steady development. The share of the United Kingdom in hardware and cutlery declined from 68 to 65 per cent. in spite of an actual increase of 12·6 per cent. in the value of the trade, while Germany's share has risen to close on 16 per cent. of the value of the total consignments.

The prices of metals have been so high during 1906-7 that it is not surprising to find a diminution in the quantities imported. The enormous rise in the price of copper all over the world is due to activity in many industries, but mainly to the extended use of electricity. Brass, as well as copper, is used for household utensils, and this item increased 3·3 per cent. in quantity and 9·1 per cent. in value.

Iron and steel showed exceptional activity throughout the world in 1905-6, and this was still greater in 1906-7. The imports of the two metals into India were as follows:—

Year.	Iron. Rs.		Steel. Rs.		Total. Rs.
1905-6..	3,40,76,911	..	3,23,62,181	..	6,64,39,092
1906-7..	4,31,83,326	..	3,23,96,882	..	7,55,80,208

The arrivals of steel from the United Kingdom increased by 18·7 per cent., and now represent 63 per cent. of the total quantity imported, as compared with 54 per cent. in 1905-6. Her share in the total value rose from 61·5 per cent. to 70·53 per cent., or 5½ lakhs of rupees. In iron she increased her shipments to India by 19· per cent., and in steel by 12· per cent., while Germany and Belgium receded largely in both departments.

The most notable development in Great Britain's shipments occurred in galvanised sheets and plates, which increased over 26,000 tons in spite of a rise in price. In this class the Continent of Europe scarcely competes, but in plain sheets and plates Germany and Belgium did fairly well in 1906-7, and still better in the previous year.

There is probably no business in which combination has been carried further than in the iron and steel trade, and the past twelve months has seen fresh developments of this nature, details of which scarcely need review in these pages.

Lead, like all other metals with which the electrician concerns himself, has shown extraordinary price developments in the past two years, and the Indian consumption has declined to the extent of 28 per cent. in quantity and 16 per cent. in value, the average price having risen 17 per cent. Tin is associated with copper in certain industries now exceptionally active but of course to a much less extent. It is estimated that the production of tin in 1906 was about 98,000 tons and the consumption about 99,000 tons. About half of the production is derived from the Malay Peninsula and Archipelago and it is from this source that India derives most of her supply.

The steady increase of the imports of machinery is an indication of sound economic development. Bombay takes the first place among the Indian provinces, Bengal's receipts having declined 3·1 per cent. The totals of the various classes of machinery imported into India in the last two years have been (in thousands of rupees) :—

	1905-6. Rs.		1906-7. Rs.
Textile	2,48,98	..	2,27,45
Steam engines and parts.	1,00,33	..	1,31,13
Electrical	23,78	..	27,04
Mining	7,46	..	6,21
Other descriptions.. ..	1,12,00	..	1,88,05

In railway material, the progressive expansion in imports continues and the figures attained the highest level on record, *i.e.*, 849 lakhs of rupees, indicating an increase of 26 per cent.

In regard to chemicals and drugs the year under review was one of high value. Camphor in particular stands at the highest value known in thirty years, and although a synthetic camphor suitable for the celluloid industry has been produced in Germany and has given rise to an important Customs' dispute in the United States, it does not yet appear that a medicinal camphor can be artificially produced at a profit. The quinine trade has been extraordinarily dull, and 7d., the lowest price on record, held good for weeks.

As to the Indian tobacco industry, one of the few good auguries is the decline that has appeared for the first time in the importation of foreign cigarettes and the hardening of prices. On an average the consumption of cigarettes represents five per head of the population of British India, but the consumption of the imported article is still insignificant as compared with the consumption of the native *beri*. The imports of aniline and alizarine dyes improved slightly but the value declined. These products are mainly derived from Germany.

Oils.—The total value of all sources of oil imported in 1906-7 was Rs. 242 lakhs, or 8 per cent. more than in 1905-6. Of this total 80 per cent. represents kerosene. Excluding Burma's unascertainable internal consumption of indigenous oil, India in the last three years has absorbed some 110,000,000 of gallons of kerosene per annum, and it is known that its use is spreading. Russia, which in 1904-5 supplied 53 per cent. of the imported kerosene, now furnishes only 4½ per cent., owing to disturbed conditions in the productive regions, and the damage is so great that it cannot well be quickly repaired. On the other hand, the United States, which in 1904-5 supplied less than 10 per cent. of the total, now sends 54 per cent., while Sumatra holds the second place.

The increase in the imports of foreign coal reflects at once the activity of India's industries and railways during the year, and the large expansion that took place in coal movements throughout the world. For many years there has been a general tendency in India to substitute country coal for the imported article, but two years ago there was a recovery, and again in the year under review there has been an increase of 43 per cent. in quantity and 54 per cent. in value. The net increase is more than accounted for by the additional consignments from the United Kingdom. Imports of raw silks and raw cottons show diminution as compared with 1905-6.

Coming to manufactured articles, the imports of cotton goods in 1906-7 were restricted as a result of various influences operating simultaneously. These were—(*a*) the high level of prices; (*b*) the dearness of food grains and the consequent contraction of the people's purchasing power; and (*c*) the movement for the preference of indigenous products. The firmness of the world's market for British cotton goods is shown by the fact that enormous as was the exportation from the United Kingdom in 1905 it was largely exceeded in 1906, and this although India took something like one million sterling's worth less. The Swadeshi movement, or boycotting of English goods, counted for something in connection with this general contraction, but very much less than the other factors mentioned.

In yarns the decrease was one of over 8,000,000 lbs. or 17·8 per cent. in quantity and 5·9 per cent. in value. No less than 93½ per cent. of these come from the United Kingdom.

The imports of cotton fabrics represent 34·8 per cent. of the total imports of private merchandise against 37·9 per cent. in 1905 6. The value decreased to the extent of 3·39 per cent. A detailed analysis of the imports would be too technical for these pages, but it is interesting to note that the United Kingdom supplies 99·3 per cent. of the grey goods, 98·25 per cent. of the bleached goods, and 95·4 per cent. of the coloured goods imported. All these percentages are better than those shown in 1905-6.

The decline in imports of silk goods, which appeared in 1905-6, has continued in the following years. In woollen goods, as in several other products, the year 1906-7 will be remembered as a time of high prices and contraction of imports. Also under the head of apparel, which includes boots and shoes, there was a falling off of 4·7 per cent. Among the other miscellaneous items which go to make up the head of "Other manufactured goods" mention may be made of carriages and carts, which increased 20½ per cent., and which includes motor-cars and motor-cycles.

Viewing the imports *en masse*, it is interesting to note that the chief articles according to value are cotton manufactures, sugar, iron and steel, machinery and mill work, railway material, hardware and cutlery, mineral oil, provisions, apparel, woollen manufactures, silk manufactures and spices, all in the order named.

With regard to the country of origin whence the goods come, the United Kingdom of course stands far and away ahead of all others. The percentage of goods, according to value, was 66·3 in 1902-3, and 66·8 in 1906-7. Germany comes second, *longo intervallo*, but her percentage has progressed materially from 2·7 for 1902-3 up to 5·3 in 1906 7. The third place is now held by Belgium, whose percentage was 3·9 five years ago, and is now 4·0. It is probable, however, that when the improved system of record comes into operation a good deal of what is now registered as Belgian will have to be credited to Germany.

Exports.

The general development of direct communication between various parts of the world tends to diminish the trade of *entrepôts*, and the decline in India's re-exports in 1906-7 amounted to a little over 1 per cent.

The value of Indian merchandise exported in 1906-7 was 173 crores of rupees, as against 158 crores in the previous year, the increase being thus one of 9·4 per cent. These exports consist mainly of raw agricultural produce which increase in good seasons and diminish in times of shortage. But other causes operate of course and sometimes the reduced export of food grains may result from smaller production or larger internal consumption.

Among articles of food and drink (which altogether exhibited a net decline of 2 crores of rupees in value), Indian coffee makes a bad show, the exports having declined 36 per cent. in quantity and 43 per cent. in value. In the rice trade the most salient features were the strong internal demand, high prices, the large shipments from Burma to India proper, and the substantial diminution (10 per cent. in quantity) of exports to foreign countries. On the average of the last five years the value of the wheat exported represented 32¾ per cent. of the exports of all food grains, and 5¼ per cent. of the total value of Indian merchandise exported. As the supplies of one year are derived from the crop of the previous year, and there was much drought and hail in 1905-6, the exports of the year under review fell short, and were only 85½ per cent. in quantity and a shade less in value of the previous year.

In 1904 India was the largest contributor to the wheat supply of the United Kingdom, but in 1906 it fell back into fourth place, being below the United States, Russia, and Argentina. The only other considerable purchaser of Indian wheat in the year under review was Belgium, but she took only 70 per cent. of her share in 1905-6, while France also reduced her takings. The shortage of wheat and continued high prices necessarily restricted the exports of wheat flour. The exports go mainly to Aden, Arabia, Mauritius, East Africa, the Straits Settlements, and Ceylon. It is unfortunate that Indian millers should have been incapacitated from competing for a share in the abnormal Chinese demand of recent months by which certain of their rivals have profited considerably. Food grains other than rice and wheat declined in the aggregate by 28 per cent.

For tea the year under review has on the whole been the most prosperous on record. The reduction of the British duty to fivepence and the increase in the Russian demand helped to sustain the market, and the demand was stimulated by a contraction of some 3,000,000 lbs. in Ceylon's production as a consequence of unfavourable weather and by a shortage in China shipments. The area and production of tea in India have both increased for many years, but the latter has developed much more rapidly than the former. Since 1902 the increase of the former has been 1 per cent., but the production is believed to have increased by over 26 per cent. It is interesting to note that the joint stock capital engaged in the industry amounts to over 14½ million pounds sterling, more than 12¼ million pounds of this belonging to companies registered in London. This gives an average joint stock capital of £27 per acre, but of course takes no account of private capital invested therein.

The quantity and price of tea exported in 1906-7 constituted a record, the increase being over 9 per cent. in the former and 11½ per cent. in the latter. The United Kingdom took only 5½ per cent. more

than in the previous year, her share being relatively on the decline. Canada came next, and Russia (whose share expanded largely) third, Australia being fourth.

One of the most curious features of the exports of Indian metals and manufactures is the well-known output of manganese ore, which represents 77½ per cent. of the total increased value of the head referred to. This abnormal activity is due to the continued restriction of the Russian output of the ore, while the added facts that the greater part of the exports from India is superior in quality to the Caucasian product, and the exceptional activity in the steel industry during the past twelve months, have altogether rendered the business extraordinarily profitable, the shipments being mainly to the United States and Belgium in the order named.

The opium trade during the latter part of the year 1906-7 was largely influenced by the proposals of the Chinese Government for its ultimate abolition and for the early doubling of the import duty. The export of Malwa opium to China has been declining continuously from 35,000 chests in the later eighties to 12,991 in 1906. But so far as the comparison of the whole trade for 1906-7 with that of the preceding year is concerned, there was a net increase of 3,338 chests, due to the enlarged shipments from Bengal.

The trade in Indian tobacco, unmanufactured and manufactured, is feeling very severely both at home and abroad the competition of America, both as a grower and as a maker of cigarettes, and of certain European countries as producers of cigars. Nevertheless the shipments of the unmanufactured product grew by 60 per cent. in quantity and 46 in value, while the manufactured increased 14 per cent. with a decline in specific value of 1·4 per cent. The largest quantities of Indian cigars are taken by the Straits Settlements, the United Kingdom, and Gibraltar.

The year 1906-7 brought some encouragement to indigo planters, for the results obtained from the Java-Natal seed have left no doubt as to its superiority, and a larger area was sown with it for the current season. The declines have been in ten years nearly 80 per cent. in quantity, and 62 per cent. in value. In 1906-7, however, there was a recovery of 12½ per cent. in quantity, and of 19½ per cent. in value.

Oils (animal, essential, mineral, and vegetable) showed in 1906-7 a further decline of 14½ per cent., the greatest falling off being in mineral oils. Vegetable oils have also receded by 13⅝ per cent., almost the same percentage as gauged their fall in the previous year.

The exports of coal from India have developed enormously since 1885. In 20 years the average exports have grown from 16,524 tons to 576,278 tons per annum. In 1906-7 they attained 940,054 tons with a value of 76 lakhs of rupees, which means an advance of 12·28 per cent. in quantity and 15·75 per cent. in value on the exports in 1905-6. Among foreign buyers of Indian coal, Ceylon retains the first place, the Straits Settlements and East Africa coming next. India still takes some 250,000 tons of coal and coke from abroad, but the use of Indian coal in the power-use industries of the country is nevertheless almost universal.

The exports of raw cotton represent 26·94 per cent. of the whole value of Indian raw materials exported. The trade is governed primarily by Indian crop results, and secondarily by the relation of textile activity in Europe and the United States to the supplies available in America and Egypt. In these respects the season of 1906-7 was extraordinarily favourable. Prices were somewhat higher than in 1905-6, and although the margin of profit was perhaps less than in that year, the textile trade throughout the world—with the exception of Russia—was remarkably active. So far as the export from India was concerned there was only a slight, practically negligible, increase in quantity accompanied by an increase of nearly 3 per cent. in specific value. The countries whither the cotton is exported are Japan, Germany, Belgium, Italy, Austria-Hungary, and the United Kingdom, in the order named.

The exports of raw hides and skins represent in value 6·3 per cent. of the entire exports of Indian produce. The strong demand for raw hides which was noticed in last year's review continued in 1906-7, and then rose by 15·6 per cent., and by 22·46 per cent. in value. The exports of raw skins decreased by 13·78 per cent. in quantity and 7·74 in value.

In regard to jute, the year under review has been one of extraordinary activity and unprecedented profits. Raw jute now represents 32·92 per cent. of the total value of Indian raw produce exported, but the increase of percentage is due in part to a decline in the exports of certain other classes. The world's consumption of raw jute is believed to be about 29·3 million cwts., and India retains a virtual monopoly of the article, her out-turn in 1906-7 being 31¾ million cwts., indicating a steady and material increase during the last few years. The average value in the year under review was 16·81 rupees per cwt., being nearly double what it was in 1902.

Seeds represent nearly 16 per cent. of the entire exports of raw produce, and in the year under review they increased 12·26 per cent. in value and about 9·3 per cent. in specific value. The various items are linseed, rape, cotton, sesamum, ground nuts, castor and poppy, and France, the United Kingdom, Germany and Belgium are the largest buyers.

In silk there has been a marked rise of price everywhere, ascribed to improved consumption, combined with a shortage of two million kilos in the 1905 crop. The exports of raw silk from India increased 9·2 per cent. in quantity and 21·7 per cent. in value: in reeled mulberry silk there was an all-round drop of 10 per cent. in specific value, arising largely from the inferiority of shipments from Bombay.

The unprecedented activity of shipbuilding in 1906-7 and the dearness of possible substitutes

caused a further rise in the values of teak. Exports decreased through greater internal demand.

The world's wool markets have been strong throughout the year, with a gradual and unwavering increase in price exceeded only in 1882, when the average price was £17 10s. The exports from India, in 1906-7, were nearly twice as much as in 1882; they rose 8 per cent. in quantity, constituting a progressive record for the fourth year in succession.

Among articles manufactured and partly manufactured, the most noticeable feature is the decline in the export of cotton yarns and goods, which amounted to 225 lakhs (£1½ millions). In cloth a decline was to be expected as a consequence of the Swadeshi movement, while the Chinese demand for yarn was paralysed by the famine in that country, and the figures in the Straits Settlements reflected the general conditions in the Far East. On the other hand, the trade with the Levant has responded in an encouraging way to certain renewed efforts made in that direction in recent months.

The number of cotton mills at work in British India on the 31st March, 1907, was 210, of which 172 were joint stock concerns with a capital of £723,274, and 12·8 crores of rupees, or over 9¼ million pounds sterling. During the year 1906-7 there were registered ten new textile concerns with a nominal capital of 95·15 lakhs of rupees, and new capital to the extent of £372,079 in all was raised by existing companies. The additions of plant in the same year amounted to 250,790 spindles and 7,186 looms, by far the largest proportion of these being in Bombay.

The exports of jute manufactures in the three years ending 1905-6, represented 34·57 per cent., or more than one-third of the total exports of Indian manufactured articles. In 1906-7, the percentage rose to 41·53. The diminished exports of wheat became more marked than in the preceding year, and there was less activity in other articles of export for which bags are required. Nevertheless, the installation of fresh jute-spinning machinery continues, and the percentage of increase in spindles was 8·46, and in that of looms 9·56. The total value of jute bags and cloth has increased from 871 lakhs of rupees in 1901-2, to 1,571 lakhs in 1906-7. The largest buyer of Indian jute fabrics is the United States, which, because of her heavy import duty on made bags, takes her supplies mainly as cloth. In 1906-7, however, she took bags to the value of 48 lakhs of rupees, as compared with 16·21 lakhs in the previous year, an increase of about 200 per cent. The largest single buyer of bags is Australia, which increased her demand by 11·8 per cent., while the growth of nearly 50 per cent. in the exports to the United Kingdom is satisfactory, considering she also largely augmented her demand for cloth. Silk manufacture continues to decline; the scattered and unorganised condition of the silk industry, however, prevents its commanding attention commercially, and efforts are being made to develop it on the lines of co-operation between the weavers. Exports of woollen manufactures increased by 10·48 per cent. in 1906-7, carpets and rugs forming by far the most important part.

The continued activity in the leather trade of the world has led to a further marked increase in the quantity of tanned hides and skins, and to a further considerable rise in the average values. In the former the advance was one of 8·85 per cent. in quantity and 11·73 per cent. in value, with an enhancement of the specific value by 2·65 per cent., in addition to 14·6 per cent. in the previous year, and 14 per cent. in 1904-5. In the case of tanned skins the exports increased by 8·33 per cent. in quantity and 28·96 per cent. in values. The United Kingdom takes the bulk of these goods, but it is known that there is a movement in America for repeal or reduction of the import duties into that country. Lac has risen continuously in recent years as a consequence of activity in the electrical industry and increased demand for high-class varnishes. The United States maintained and confirmed its leading position as a buyer of shellac and button lac.

Distribution of Trade.

With regard to the countries of destination of the Indian export trade, it is noteworthy that the United Kingdom, with 26·9 per cent., has slightly improved her position, but is still short of the percentage (37·1) of 1903-4. The feature of the table is the assumption by Germany of the second place, in consummation of the steady advance of the past years. China drops into third place (instead of second), and France now takes precedence of Japan.

Gold and Silver.

The net imports of gold which, as well-known to students of India's economic statistics was always (as well as those of silver) considerable, increased from 45·8 lakhs of rupees to 1,485½ lakhs (£9,904,000), which is the highest on record.

The imports of silver attained the unprecedented level of 2,604 lakhs of rupees, and there can be no doubt that the heavy demand for the metal which has attended the commercial development of the silver-using East is the prime factor in the rise of price recorded above. The exports increased but were far below the average, and the net imports, amounting to 2,400 lakhs rupees, largely exceeded the figures for any previous year.

Shipping.

While the net increase on the value of imports and exports of merchandise by sea amounted to 7·2 per cent. of the total for the previous year, there was an increase of 11·61 per cent. in the tonnage of shipping that entered and cleared from Indian ports. The average tonnage is constantly increasing as is well known, and is now 1,477, and for steamers only, 2,266. Taking the sailing ships alone, the average tonnage is only 90 tons, which indicates that the sailing vessels are only small native craft.

The entries from and clearances to the United Kingdom were 3,121,861 as against 3,140,281 tons in 1905-6, while those from and to British Possessions other than the United Kingdom increased from 4,784,555 to 5,650,916 tons. The increase was, therefore, over 2 per cent. in the case of the parent country, while the increase in the case of the dependencies was over 3 per cent.

FRONTIER OR LAND TRADE.

The bulk of India's foreign trade is and always must be sea borne, the value of the trade across the land frontiers of India being equal to only 5·14 per cent. of the other. The foreign land trade has, however, after steady progress attained fairly substantial dimensions, being now about 11¾ millions sterling.

THE ICE PROBLEM IN ENGINEERING WORK IN CANADA.*

In Canada the physicist has excellent opportunity to study on a grand scale the operation of the natural laws governing the formation of ice in the many forms met with in the large and often turbulent rivers. To the engineer the problem is more serious, for the development of the vast water powers of the country must include means for combating the ice troubles which arise each winter. The conditions which must be met during the winter months are sometimes very serious, when ice is forming rapidly, and ice-bridges, dams, and shoves may change the whole character of the levels and channels in a single night. Rivers are known to have been turned entirely out of their course to seek new channels during a winter of unusual severity, and in some instances the reversal of a rapid is of yearly occurrence. Nowhere can one witness a more wonderful sight of the delicate poising of the forces of Nature than in one of the Canadian rivers in winter. The steadiness of the temperature of the water throughout the ice season is a matter of great interest. It seldom varies more than a few thousandths of a degree from the freezing point even in the severest weather. This is true for rivers flowing too swiftly for surface ice to form, as well as for the quieter streams protected by an ice covering.

In general three varieties of ice are distinguished, and present characteristics brought about by their method of production. Surface or sheet ice forms over the surface of quiet lakes or rivers, and is helpful or not depending on the particular conditions. Spicular ice, or as it is called in Canada, frazil ice, is formed by surface agitation in the more turbulent rivers, and in waterfalls, and accumulates in great quantities in the quieter portions of the stream where it is carried by currents. It varies in size from thin plates to fine needle crystals depending on the degree of agitation of the water, and of all the forms of ice it gives the most trouble in hydraulic work. Anchor- or ground-ice is the most interesting form on account of the fact that it grows along the bed of a river which is not covered by a surface sheet. It is formed in two ways: by the cooling of the bottom by the radiation of heat during cold clear nights, and by the freezing of frazil-ice carried down by the currents of water when in a supercooled state. A bright sun has a great influence on the ice, and as soon as its rays are sufficiently high to penetrate to the bottom, the ice is detached and rises to the surface. In so doing it frequently brings up stones or boulders of considerable size to which it is attached.

A study of the temperature conditions in the water during the production of these forms of ice shows that the freezing is accompanied by a small temperature depression in the water, amounting to a few thousandths of a degree from the freezing point.* During severe cold weather the water is thus thrown into a slightly supercooled state, during which time the ice crystals grow rapidly by continued freezing, and give rise to the agglomerating stage, when they possess adhesive properties and form lumps and spongy masses. In this condition the ice is dreaded by power users, for it quickly adheres to the rack-bars and to the machinery of the wheel-gates and turbines. In a short time it interferes with the operation of the wheels, and may at any moment cause a temporary cessation of operations. Fortunately, it is only a minute temperature depression which brings about these conditions, and methods of artificial heat applied about the affected spots relieve the situation in a short time. An intelligent use of artificial heat, specially at night time when supercooling is most common, is found valuable in preventing any interference with the normal operation of a power house. It is not necessary to warm the entire volume of water passing through, which would be very costly and difficult, but by applying the heat in the racks or wheel cases, or blowing steam about the affected parts, the ice is prevented from obtaining a foothold. The ice is as effective as so much water in producing a head, hence the necessity of passing it through, and never allowing it to freeze to the metal surfaces of the machinery. It is safe to say that where it is possible to apply even a small quantity of heat directly to the machinery and racks, a condition of affairs may be done away with which for many years has been regarded as involving inevitable interruption to the continuous operation of a plant.

There are other causes at work, however, to interfere with the operation of power plants, which depend on the particular spot where a power-house is located. Rivers like the St. Lawrence at Montreal are subjected to winter floods, occasioned by the accumula-

* Abstract of Paper read by Howard T. Barnes, D.Sc., F.R.C.S., Associate Professor of Physics, McGill University, Montreal, before Section G of the British Association, at Leicester.

* Cases are known, however, where anchor-ice was formed by copious nocturnal radiation when the water was slightly above the freezing temperature.

tion of frazil- and disintegrated anchor-ice. Where-ever open water or a rapid occurs above a surface sheet of ice, large quantities of frazil-ice are carried under by the currents, and settle upwards in the quieter parts. Large hanging dams of spongy ice are thus produced, which so reduce the available waterway as to cause serious changes in levels. Sometimes the channels become blocked entirely, and then the water backs up sufficiently to clear the ice away and produce a shove. A tremendous upheaval results, and large masses of ice are piled on high for miles around, often doing much damage.

It is well known that the most effective prevention to the formation of both frazil- and anchor-ice is the protection afforded by a surface sheet of ice. If a power-house is located on a river normally frozen over, with no stretches of open water above, no ice troubles are experienced. When this is not possible, artificial intake canals are usually constructed, in which the water flows sufficiently slowly to freeze over. If the canal is fed from the open river, booms and crib-work are resorted to in order to deflect much of the ice. If the inflowing water current is sufficiently rapid to draw the frazil under the surface ice, it is often necessary to cut artificial channels to allow of sufficient water for the wheels. Thus a surface sheet may prove to be disadvantageous. So many and varied are the conditions to be met with in the location of a power-house that no set of rules can be given to meet the general case. It is only by a thorough knowledge of the laws underlying the formation of ice that means may be found to cope with any particular situation. It may safely be said, however, that the ice problem in Canada is no bar to the future development of her vast water powers.

THE HEATING OF COTTON-CAKE AND ITS PREVENTION.*

Oil-cake made from cotton-seed is apt to heat under certain conditions. It is the experience of oil crushers at home that cake made from Indian cotton seed is peculiarly liable to this accident. Recent advices show that the evil is being mitigated by improved practice in the manufacture and storage of the cake; but large holders in Europe recognise that there is a certain risk in keeping heavy stocks under ordinary conditions in summer time. This, being true of temperate climates, is doubly true of those that are tropical or subtropical, and where the air is humid. In some dry parts of India it is stated that the danger has practically not been experienced, but in other parts it is well known. It would be increased by the conditions of storage in the close hold of a ship

On the other hand, the virtues of cotton-cake as a cattle feed are as yet little recognised in India; and, although the direct use of oil-cakes as manure is increasing in this country, such direct use is wasteful. The best results are obtained in other countries by feeding the cake to cattle, and employing the dung as a "fertiliser." This practice applies mainly to the feeding of fat stock under conditions not commonly encountered in India, and it is uncertain how far it could be adapted to the circumstances existing here. At present, therefore, it is impossible to postulate such an internal demand as would take off all the cake to be produced by a considerable cotton-oil industry in this country. But an oil mill of the ordinary kind relies on the cake for a very great part of its receipts. Without adequate receipts on this account, it is improbable that such a mill could be profitable; and for this reason anything that prevents the shipment of surplus stock to external markets is a serious matter.

It is thus clear that at the present juncture, one o the most important practical problems connected with a cotton-oil industry in India is the prevention of heating. There is no doubt that the heating is due to bacterial action or fermentation. But we know that the interior of a seed is free from such bacteria; otherwise it could not live and germinate as a seed. Therefore the bacteria must be in or rather on the husk or shell of the seed. This is borne out by the statement that decorticated American seed yields a cake more immune than is obtained from undecorticated seed. The removal of the husk apparently entails removal of the chief source of contamination. It does not, however, eliminate all risk; for in the process of decortication the machinery must become contaminated by contact with the husks and communicate the germs to the kernels as they pass to the mills.

There is in the United Kingdom no plant for the decortication of Indian cotton-seed. It is, therefore, impossible to say what truth there is in the suggestion that decortication becomes more difficult by the lapse of time between picking and treatment. In America it is the practice to decorticate as soon as possible. But even if decortication were successfully and generally carried out in India, the fact of the contamination of the kernel by contact with the machinery forbids any hope that heating could by this means be really prevented. It need scarcely be added that all analogy shows that in India the fermentation would occur much more rapidly and intensely than at home Therefore, whether the husk is to be left in the cake, or to be brought in contact with machinery that will afterwards contaminate the kernels, it is evident that this husk ought to be sterilised at the outset.

It might be possible to use some kind of antiseptic if the seeds were free of fluff or lint; but we are confronted by the fact that the fluff on Indian seed is abundant and peculiarly tenacious. In view of this fact there can be no doubt that the danger of tainting the oil or rendering the cake unpalatable to cattle by the use of an antiseptic, is greatly increased by the quantity of absorptive and retentive fluff that covers the seeds.

* From the *Indian Trade Journal* (the organ of the Indian Commercial Intelligence Department, Calcutta).

This fluff has hitherto constituted the most commonly recognised objection to Indian cotton-seed, both from the crusher's and from the feeder's points of view. And although it is evident that the most intelligent feeders at home have now recognised that its evils have been absurdly exaggerated, certain authorities continue to reiterate their criticisms on that score. It would, therefore, be desirable that the process to be employed for external sterilisation of the seed should be such as will remove the fluff.

Heat is probably the best agent for destroying bacteria. But to expose an oil seed containing albuminoids and other sensitive bodies to a high temperature for any length of time would be injurious. Fortunately the husk is a good non-conductor, and it is, therefore, open to us to consider whether sterilisation might not be accomplished by a brief exposure of the seed to the temperature of combustion, followed by subjection to conditions rapidly carrying off the heat acquired in the process.

The fluff on Indian cotton-seed is so inflammable that under certain conditions it can be made to burn almost explosively. It seems possible, therefore, that it might be ignited and consumed in such a manner as to do exactly what is wanted. The proposal, in fact, is to sterilise the husk of Indian cotton-seed by the act of removing the fluff with a quick blast of fire, the fuel consisting mainly of the fluff itself.

The apparatus would probably consist of a shaft of suitable height, into the head of which the seed would be admitted sparsely from a closed hopper. Near the head of this shaft, and on one or more sides of it, there would be a passage or passages leading to the outer air, or to a stiveroom. In the shaft, an upward current of air of a suitable velocity would be maintained, either by an aspirator in the passage leading to the stiveroom, or possibly by the combustion of the fluff within the shaft. Opposite to, or slightly below this passage there would be an arrangement for projecting into the shaft a blast of smokeless flame. Below this again the shaft would contain baffles or other appliances for the friction of the seed after scorching. The intention is that the seed, in falling down the shaft, should encounter an upward or transverse current of air of such velocity as would carry off loose dust, lint, and other impurities of a light character. It is probable that seeds to which a very large quantity of fluff or lint adhered would also be drawn out at this point. The seeds that remained would in their further descent come in contact with the blast of flame, and would by the upward current of air be retarded in their passage through that flame, for a moment proportionate to the greater or less quantity of fluff adhering to them. The air current would rapidly carry off the products of the combustion which would probably be fierce. As soon as a seed became free of lint, and so offered a diminished resistance to the ascending air-current, it would drop out of the focus and continue to fall through air at a natural temperature. The air at this point might be dry, and this would facilitate the complete combustion of any lint that might still adhere to individual seeds. At the same time all dust and ash would be carried off, and the seed would be partly cooled. At the head of that section of the shaft which is furnished with baffles it would probably be well to admit part of the air furnishing the upward current. The air admitted at this point might, as we say, be dry. The effect of the admission of air at this point would be that below it the current would have less velocity, with the result that gravitation would make the seed impinge upon the baffles with such force as to knock off any traces of ash. It might be found expedient that the air admitted at the base of the shaft should be humid, in order to expedite the cooling of the seed.

In effect, the seed ought to reach the foot of the shaft cool, free from fluff, and sterile. It is improbable that anything would be gained by decorticating such seed; but in any case neither the decorticating plant, nor the ordinary crushing plant could acquire germs from a sterile husk, and it follows that the cake made from seed so treated would probably not heat.

This general idea is published in the hope that some firm interested in appliances for the crushing of cotton-seed may be induced to test the practicability of the process.

THE SURVEYS OF BRITISH AFRICA.*

It is perhaps not generally known that during recent years a good deal has been done to ensure the systematic mapping of British Africa. There are at the present moment properly organised survey departments in the Anglo-Egyptian Sudan, Uganda, East Africa, Southern Nigeria, and the Gold Coast. In addition, an exact topographical survey is in progress in the Orange River Colony; and in the Cape Cape Colony a military reconnaissance survey has been at work for two and a half years. The annual cost of the surveys above enumerated amounts to some £80,000. An account of the progress made, the scales adopted, and the history of the surveys will be found in a Colonial Office Annual Report, No. 500, entitled the "Surveys of British Africa." Unfortunately, official reports have a limited circulation and public departments cannot very well advertise their achievements. As a consequence, all this systematic work, which produces surveys of a permanently valuable character, is largely unknown to the geographical world. It is clearly desirable that that section of the public which takes an interest in the matter should be informed as to the steps which are being taken to map and explore British Africa, which, it may be noted parenthetically, covers an area of about 2,690,000 square miles. During the current year about 45,000 square miles will have been topographically surveyed, and to this must be added a large

* Abstract of paper read by Major C. F. Close, R.E., before Section E of the British Association, at Leicester.

number of compilations, the surveys of boundary commissions, and cadastral surveys. The maps are put on sale as they are published, and can be purchased from the usual map sellers and agents. Anyone desiring special information on the subject is advised to write to the Secretary, Colonial Survey Committee, Colonial Office.

NICOTINELESS TOBACCO.

What is popularly known as "Caporal doux," or the so-called "nicotineless tobacco," in France, is simply ordinary caporal tobacco which has been treated by washing with water until the ordinary proportion of 2½ per cent. of nicotine has been reduced to 1 per cent. In this form it is used for smoking in pipes and for the manufacture of cigarettes, which find a certain favour among smokers who prefer a light flavour, or who by reason of nervous or cardiac weakness are wary of nicotine. Ordinary caporal is a mixture of French, American, and Oriental tobaccos, prepared by the Régie or Government establishments, which have a monopoly of the manufacture of tobacco, cigars, and cigarettes in France. It has a somewhat rank, but not unpleasant flavour, and is the cheapest and most popular form of tobacco used in France. The American Consul-General in Paris says that about eight months ago the French Government, finding that there was a growing demand for a so-called "nicotineless tobacco," which had been made on a small scale by certain druggists, and was also manufactured in Belgium, began the manufacture of a similar product by denicotinising caporal tobacco through the action of water, which, in reducing the proportion of nicotine from 2½ to 1 per cent., also washes out other ingredients, so that the weight of the tobacco is reduced, according to the quality of the leaf, from 15 to 30 per cent. It is this loss of weight rather than the actual expense of the process which constitutes the cost of denicotinising, and explains the fact that ordinary caporal tobacco is advanced so much in value when denicotinised. The process of washing is simple, and is facilitated by the use of automatic machinery, but it requires careful and constant supervision by a skilled and trustworthy workman, in order that a uniform product containing the specified percentage of nicotine may be obtained. It is too soon to form any conclusion as to the extent to which denicotinised tobacco and cigarettes may be used in France. It is now on sale in Paris and in eighty other municipalities throughout the country. During the four months from January 1st to April 30th last, there were sold by the Régie to dealers in Paris 26 tons of denicotinised tobacco, and 5 tons, or 50,000,000 cigarettes, made from the same material. To smokers accustomed to full-flavoured tobacco the smoke of "caporal doux" is somewhat insipid. Its one advantage is that 25 cigarettes made of it contain only the same amount of nicotine as 10 of ordinary "caporal," and its narcotic action upon the heart and nervous system is proportionately reduced.

HOME INDUSTRIES.

Enterprise in Agriculture.—*The Times* of October 5 contained, under the heading "An Agricultural Success," a most interesting contribution from a correspondent, who describes what has been done in recent years by Mr. A. J. Keeble, of Wereham-hall, Norfolk, in reclaiming practically waste land. Mr. Keeble had done a good deal in this way before he went to Stoke Ferry. In one case he had dealt with some 687 acres, which he divided into sixteen lots, and in another with 3,780, divided into 191 lots. His operations on these two estates yielded him a profit, out of which to a large extent he was able to acquire his Norfolk residence without trenching on original capital, and it is with these freeholds that the correspondent referred to above concerns himself. The estate is 12,771 acres, or about 20 square miles. The land was practically derelict when Mr. Keeble took it over. A large portion of it, which be bought from the Duchy of Lancaster at £2 17s. 6d. per acre, was absolutely so. Wissington-hall, which he made his home before he acquired Wereham, was derelict. "Saverals," a farm of sufficient importance to be marked even on the smaller maps, was derelict too. To-day these 12,771 acres are in the occupation of 48 farmers, whose average holding is 255 acres. Mr. Keeble's first care is to find what size holdings suits any given district, and, believing that men are the essentials, he does his utmost to make the holding for the man. Thus, a middle-aged farmer, with a couple of grown sons, will do best by tackling a larger area than another dependent on two hired men.

Mr. Keeble, on acquiring his properties south of the line from Downham to Stoke Ferry and north of the line from Ely to Brandon, saw that the cultivators of this district would be impotent if unable to find a proper outlet for their produce. He had acquired land at £2 17s. 6d. per acre freehold, strips at even less, and he had paid as much as £17 per acre for special land. But between these prices he had always found sellers, and he held a compact area suitable for development. To develop it required a private railway. Mr. Keeble built one. "The railway, between five and six miles in length, is not a light railway as that term is usually understood; its gauge is that of the Great Eastern, with which, at Abbey Station (short for Dereham Abbey) it connects; its trucks, therefore, run straight on, and when Mr. Keeble hires a special on the Great Eastern, he or his tenants, mostly, of course, their produce, travel 'through' from open fields in the heart of Norfolk to Liverpool-street or Stratford. The bridge over the Wissey is of strength and size which surprise the most casual glance. The constructor — for Mr. Keeble is his own engineer as he is his own architect —explains that he has made the whole line in such a manner that a Great Eastern train could run on it. The bridge will carry an express." The sidings of this unique private line are at quarter-mile intervals, and every farm on the estate debouches on to the

line. The Great Eastern Railway keep up high tariffs, but allow many facilities. "Thus, if the tenants of the Keeble estates can make up—as they frequently can—an amount of stuff for the London market amounting to 100 tons—say 20 medium or 25 small trucks—the company will send a special engine to fetch this train, and give the resulting "special train" prompt passage to London, where the produce can be, and is, on sale at 5 a.m. Mr. Keeble has a salesman at King's-cross, and another at Stratford (the goods station for Liverpool-street), whose services enable his tenants promptly to dispose of produce. All sales are telegraphed, and the local grower can have his cheque for the net result at any time he pleases. The private railway has a telephone running by the side of it, and at its terminus; at a wooded house, in fields somewhere between Southey and Feltwell, messages are received throughout the day. There is a time-table on this little line, not printed indeed, but painted on a notice board. The train has a passenger coach, and farm labourers are saved all walking. The saving of exertion and fatigue that free facility gives is beyond calculation, and the telephone prevents the remotest cottager from feeling isolated. In case of ill-health, or other emergency, communication is at hand, while 'the market intelligence, with prices made,' which is wired to Mr. Keeble, at Wereham, by the London salesmen, is telephoned along the private line. It often decides the day's work, still more frequently the next day's, for these Fenland cultivators do not neglect the markets.

The land is of course exceptional; the vigour, resourcefulness, and knowledge of its owner are of course exceptional; even Mr. Keeble could not have literally changed the face of the land as he has done without having large capital at his command. It is not every landowner whose soil would respond, as Mr. Keeble's does, to good treatment, or which is so favourably placed. But when all allowances are made for exceptional conditions, the results are very remarkable.

State Afforestation.—The Government have taken a step which has been warmly welcomed generally. They have bought the estate of Inverliver, in Argyllshire, from Colonel Malcolm, of Portalloch, in order to convert it into a State forest. The estate has an area of nearly 13,000 acres. At present there are only about 90 acres of plantations, and a long time must elapse before any new timber becomes saleable. But a certain number of acres will be planted every year; the estate will be a school of forestry managed by the Office of Woods and Forests, and it may be hoped that it will be the forerunner of other similar estates. In other European countries the State has done much afforestation to the general advantages, as, for example, in the West of Jutland, where the land is singularly barren, and there is general admission that there are large areas in the United Kingdom which might be profitably planted. But it is essentially a work to be taken in hand by the Government, if it is to be done at all on the necessary scale. Individual landowners will not make, or cannot afford, the large outlay required by afforestation, outlay for which only young men could expect to reap any financial return. But the State is not hampered by such considerations, and the contraction of foreign sources of supply of timber may well encourage statesmen to take the work of afforestation in hand.

"Chilled" Meat.—Last week the first consignment of "chilled" meat, as distinguished from "frozen" meat was landed at Liverpool in what is said to have been excellent condition. It came from Buenos Ayres, where it was killed 43 days previously. Until now, attempts to carry fresh meat long distances, except at very low temperature, have been unsuccessful. They have induced "spotting" and "mildew," but this does not seem to have been the case with the present consignment, although it was carried at a mean temperature of 31½ degrees Fahrenheit, or three degrees higher than has before been attempted. The ship which brought it, the steamer *Guadiana*, has a larger capacity for carrying refrigerated meat than any other vessel afloat, namely, a total of 180,000 carcases. She was built specially for the Argentine fresh meat trade, and is fitted with the ordinary brine circulating system. The chamber is fitted with the Linley process. The new system has been introduced to obviate the deterioration of the meat due to freezing.

The Wool Sales.—Both in Australia and in London the wool sales have begun well for the pasturalists. At the opening of the sales in Adelaide there was a large attendance of buyers, and practically the whole of the offerings, which covered 20,000 bales, were disposed of at prices showing an average advance, compared with last season, of 10 to 15 per cent., for all the better classes of greasy merinos, while lamb's-wool appreciated 10 per cent., and the finer grains of cross-breds fully 5 per cent. The quality and condition of the new clip are reported to be very satisfactory. The sheep have cut very big fleeces of deep-stapled sound wool. The London wool auctions are also animated with values much as it was expected they would be. The Queensland wools, both scoured and greasy, are just what the trade wants, and with keen competition prices are up 5 per cent., and in some cases more. A portion of one big clip, grown in Queensland, has sold at prices which will make it cost about 32d. in the top. Other Queensland clips of greasy wool have been taken by France at prices which, it is estimated, will cost over half-a-crown in the top, whilst the United States are purchasing wools which, when the duty has been paid, will cost at least a dollar in the same state. At Bradford, the market remains quiet, users being unwilling to anticipate their further wants. Having regard to the monetary and general commercial outlook, prudent traders may be expected to refrain from buying more than enough to meet present needs,

Delays in Transit.—Attention was recently directed in these notes to the loss sustained by Lancashire spinners, in common with other importers, from delays in transit on the American railways. A company working from Burnley, Lancashire, and Memphis, U.S.A., which has been recently formed to sell American cotton directly to Lancashire spinners, had 5,000 bales stored in Memphis, for three months last season, after the railway company had issued bills of lading. As might be expected, the condition of the bales on their arrival in this country, after exposure to the weather for so long, was bad. The company has now opened a new compress on the Mississippi, at Memphis, this compress being built in order to remedy the inconvenience and loss consequent upon railway delay, and this is done by avoiding the railway altogether, between Memphis and New Orleans. The intention is that cotton received at the compress shall be pressed and delivered into a barge on the same day. Four days later the barges will be alongside the steamers at New Orleans, and will be transhipped without being landed on the quay at all. It is expected that in this way the vexatious and costly delays of the past will be entirely avoided. The cotton will be constantly under cover, picking and mending will be obviated, and good condition should be ensured, with delivery within a month of shipment.

CORRESPONDENCE.

SWISS STRAW GOODS INDUSTRY.

Mr. W. L. A. Gautier writes respecting a statement in the article on "Straw Goods Industry" in the last number of the *Journal* (page 1060, col. 2, ll. 2 and 3):—"I have been engaged in the industry for over forty years, and I never heard of *straw* being knotted together for plaiting. The materials which require to be knotted into long lengths are hemp and horsehair only. The short lengths of *real straw* are spliced by the plaiters in the process of plaiting. The other two materials are plaited by machinery, hence splicing is impossible in the process of plaiting."

[The American Consul at Aarau makes the statement in his report, which is objected to by Mr. Gautier, and adds that the knotting is a work requiring infinite patience and considerable skill.—Ed.]

GENERAL NOTES.

School of Art Wood-carving.—The School of Art Wood-carving, South Kensington, which now occupies rooms on the top floor of the new building of the Royal School of Art Needlework in Exhibition Road, has been re-opened after the usual Summer vacation. Some of the free studentships maintained by means of funds granted to the school by the London County Council are vacant. The day classes are held from 10 till 1 and 2 till 5 on five days of the week, and from 10 till 1 on Saturdays. The evening class meets on three nights a week and on Saturday afternoons. Forms of application for the free studentships and any further particulars relating to the school may be obtained from the manager.

Damascus.—In his report upon the trade of Damascus (Cd. 3729) Mr. Consul Dewey refers to its population. At the last census, which took place in 1906, it was put at little more than 203,000 souls, but, owing to the irregularity with which the census was taken, the figures cannot be taken as accurate. It would be proper, in the opinion of the Consul, to say that the residents of Damascus are not less than 250,000, and some authorities rate them at over 300,000 souls. Only about one-eighth of this population are Christians or Jews, the remaining seven-eighths being Moslems. As in 1895 the population was estimated at 215,000, it would seem to be increasing somewhat rapidly, but this increase is entirely among the Moslems, and is greatly due to a large influx of emigrants from Crete, the Caucasus, the Balkans, &c. The Jewish element has remained stationary at about 8,000 or 10,000, and the Christians have diminished slightly by emigration through Beirut to various parts of the world.

British Trade with Belgium.—In the course of some remarks upon the trade of the United Kingdom with Belgium, to be found in his report upon the trade of that country for 1906 and the first half of 1907 (Cd. 3277-1), Consul-General Sir Cecil Hertslet observes that British firms endeavouring to sell their goods in Belgium in many cases obtain, through the medium of a Consular officer, or the Intelligence Branch of the Board of Trade, the names of likely buyers of their goods, with whom they communicate, and in many cases establish a fair trade. Only in exceptional cases, however, is it remembered that the foreign taste in regard to certain articles is not necessarily the same as the British. The advertising of British goods in Belgium is, of course, an excellent way of making them known; but in the case of firms in a fairly large way of business, there is no better way of making their goods known than by sending travellers to Belgium to show their goods to likely buyers and to impress the merits of the same upon them. These travellers should endeavour to find out the style of article required, and British firms should be prepared to make it of the particular model required if they wish to enlarge their trade. It is in this way that German firms obtain so large a share of Continental trade. The idea of "educating the foreigner to British tastes" is not, says Sir Cecil Hertslet, generally speaking, the way to encourage him to purchase British-made goods, though, of course, in certain cases it does so.

Journal of the Society of Arts.

No. 2,865. VOL. LV.

FRIDAY, OCTOBER 18, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

FOTHERGILL PRIZE.

FOR LIFE-SAVING APPARATUS FOR USE IN NOXIOUS ATMOSPHERES.

The Council of the Society of Arts are prepared to award, under the Fothergill Trust, a Gold Medal, or a prize of £20, for the best portable apparatus or appliance for enabling men to undertake rescue work in mines or other places where the air is noxious.

It is intended that the apparatus sent in shall be submitted to practical trials and tests.

In the award of the Medal regard will be had, firstly, to excellence of design and contrivance, and, secondly, to excellence of manufacture. Credit will be given to such parts of the apparatus as are the invention of the exhibitor; the object being to distinguish the apparatus which gives the best promise of being practically useful.

Inventors intending to compete should send in a notice of their intention, together with a full description of their inventions, not later than 31st March, 1908, to the Secretary of the Society of Arts, John-street, Adelphi, London, W.C.; and in cases in which the apparatus has been put into actual use, the experience of such use should be given, and the special points of merit of the apparatus indicated.

Notice of the place to which the apparatus is to be sent will be subsequently given to those competitors whose apparatus the judges may desire to test, together with an indication of the tests, and of the manner in which they will be conducted.

Competitors intending to patent their inventions should be careful to obtain protection, as the Council of the Society cannot undertake any responsibility as regards the secrecy of the whole, or of any part, of an invention submitted to them.

The Prize will be awarded on the report of judges appointed by the Council.

The competition is not limited to British subjects.

The Council reserve to themselves the right of withholding the Prize, of extending the time for sending in, or of awarding a smaller Prize or smaller Prizes.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

DETERGENTS AND BLEACHING AGENTS USED IN LAUNDRY WORK.

BY PROF. HERBERT JACKSON, F.I.C., F.C.S.

Lecture I.—Delivered April 15, 1907.

In these lectures it is intended to deal with the subject-matter mainly from a practical point of view. Such analytical processes as are described are those which are easy of application and which have been found to give results accurate enough for the special purposes they are meant to serve.

Water is undoubtedly the most important agent used in laundries, whether it is considered as a detergent itself, as a solvent for more powerful detergents, or in relation to its use in boilers. For washing purposes there is no question that pure water fulfils all the requirements most perfectly, but as it is never procurable in sufficient quantities it is necessary to determine how far the solids dissolved in the water supply render it unfit for laundry purposes. It is well known that salts of calcium and magnesium present to any great extent prevent the economical and useful application of soaps for reasons which will be considered shortly, but it must be remembered that large quantities of other soluble salts such for example as sodium chloride and sulphate,

not only retard the action of soap and prevent the removal of dirt in a fine state of division but are objectionable in boilers. In actual practice it was found much more economical, and to give better results, to change from a water containing 116 grains of solid matter to the gallon to one with 48 grains, although the latter was four times as hard from calcium salts and the expense of the softening had to be incurred. Another reason for discarding a water holding much solid matter in solution is to be found in the character of the residue left by the evaporation of the water. This is frequently found to be markedly deliquescent, and articles of clothing rinsed in the water absorb moisture from the air and become damp very soon after they have been dried. As a rule a water residue which readily takes up moisture will be found to contain some chlorides of magnesium and calcium.

In most waters which are met with in practice the common forms of calcium salts present are calcium bi-carbonate (*i.e.*, a solution of calcium carbonate in carbonic acid) and calcium sulphate. Their action on ordinary soaps consists in the production of insoluble calcium salts of the fatty acids of the soap, with the accompanying formation of soluble sodium bi-carbonate or sulphate. Expressed in the form of a chemical equation, and adopting sodium oleate as a typical simple soap, the reaction is:

$$CaCO_3 . H_2CO_3 + 2\ NaC_{18}H_{33}O_2 = Ca(C_{18}H_{33}O_2)_2 + 2\ NaHCO_3$$

and—

$$CaSO_4 + 2\ NaC_{18}H_{33}O_2 = Ca(C_{18}H_{33}O_2)_2 + Na_2SO_4.$$

A calculation from these equations shows that 100 parts of calcium carbonate or its equivalent of any other calcium salt dissolved in water, will convert 608 parts of pure sodium oleate into the useless form of insoluble calcium oleate. Substituting any good soap of average quality for the sodium oleate, 100 parts of calcium carbonate in solution would react on about 1,000 parts of the soap. As the gallon is still used as the standard measure of volume in many industries, it is convenient for the present purpose to retain the older form of expression, and to speak of one degree of hardness as that due to the presence of one grain of calcium carbonate or its equivalent of any other calcium salt in solution in one gallon of water. Every gallon of pure water requires about 10 grams of ordinary soap before a lather can be produced, and it will be seen from the numbers given above that each degree of hardness will necessitate the addition of another quantity of 10 grams of soap. The action of magnesium salts is similar in general character to that of calcium salts, but differs in respect of the amount of soap used up and in the time occupied for the completion of the reaction. The chemical equivalent of magnesium carbonate for 100 parts of calcium carbonate is 84, but it is found that this amount is equal in soap-destroying power to 150 parts of calcium carbonate, and this must be taken into account in estimating the hardness of waters containing appreciable amounts of magnesium salts. The question of the time of the reaction with soap is often of importance. Whereas calcium salts react immediately with soaps, the action of magnesium compounds is gradual, and may be delayed considerably. In one water which contained the equivalent of 8 grains of magnesium carbonate and 14 grains of calcium carbonate to the gallon, the hardness of the water towards soap was not shown as more than 18 degrees, even after the lapse of 48 hours. Dilution with an equal volume of distilled water hastened the action, but the total hardness of about 27 degrees was not revealed until the water was heated with the soap solution to 50° Cent. (122° Fahr.). It may be mentioned here that this anomalous action of magnesium salts is by no means so marked with pure sodium oleate as it is with soaps containing also sodium palmitate and stearate. Before dealing with processes for softening waters it is necessary to consider the nature of hardness somewhat more fully, and to describe simple methods of determining the degree of hardness in a water.

It is customary to draw a distinction between temporary and permanent hardness. The former is considered to be due to the presence of carbonates of calcium and magnesium, held in solution by carbonic acid, and is described as temporary since heating the water drives off the carbonic acid gas and precipitates the carbonates as insoluble granular or crystalline powders. The latter is due to any other salts of calcium and magnesium, such for example as chlorides or sulphates which are not thrown out of solution when the water is boiled. This distinction between two kinds of hardness is convenient for some purposes, but it is misleading in connection with the use of water in boilers. The statement that calcium sulphate is not thrown down on boiling under ordinary atmospheric pressure is practically true for a water containing somewhere about 10 grains of this compound per gallon along with varying

amounts of calcium carbonate. The deposit obtained from such a water by simple boiling will be found to contain mere traces of calcium sulphate. It is quite otherwise, however, when the water is heated under pressure in a boiler. In this case, the temperature rising above the ordinary boiling point will cause the separation of a considerable amount of calcium sulphate, which mixes with the deposited calcium carbonate, and forms a hard and intractable crust in the boiler. No distinction between temporary and permanent hardness need be made so far as the action on soap is concerned. Both the carbonate and other salts of calcium and magnesium act in a similar manner, and it is only therefore in connection with softening processes that the recognition of the two forms of hardness is useful.

The determination of hardness for laundry puposes is best carried out by the well-known process of treating a definite volume of the water to be tested with a soap solution the value of which has been ascertained by means of a solution of a calcium salt of known strength. In making up these solutions it is much more convenient to use metrical weights and measures. Any good and fairly dry olive oil soap, *e.g.*, Castile soap* will be found suitable, and 10 grams of it should be dissolved in a litre of alcohol of about 40 per cent. strength. The solution of calcium salt which is to be taken as a standard is easily made by dissolving one gram of pure calcium carbonate in as small a quantity as possible of dilute hydrochloric acid, adding a very slight excess of dilute ammonia to neutralise any free acid and making up the volume of liquid to one litre by adding distilled water. (In order to be able to translate results readily into grains per gallon it is best to adopt 70 cubic centimetres or some simple multiple of 70 as the quantity of water to work upon, since there are 70,000 grains in a gallon and 70,000 milligrams in 70 cubic centimetres). The valuation of the soap solution may be made by taking 10 cubic centimetres of the standard solution of calcium chloride and diluting it to 70 cubic centimetres with distilled water. This will represent a water of 11 degrees of hardness, the extra degree being for the water itself which requires soap equivalent to one milligram of calcium carbonate before a lather can be formed. If on adding soap solution from a vessel graduated in cubic centimetres and parts of cubic centimetres with constant shaking, a lather permanent for about five minutes is formed after 11 cubic centimetres of soap solution have been added to the 70 cubic centimetres of diluted standard calcium solution the soap solution is right, and the number of cubic centimetres of it used to form a lather with 70 cubic centimetres of any water will indicate the degrees of hardness in that water. Should the soap solution be found to be stronger or weaker than the standard, it may be diluted or strengthened to bring it right or used as it is, unless it is very far out, and a simple calculation made for correction of the results. With very hard waters it is necessary to dilute them with an equal volume of distilled water, and to take 70 cubic centimetres of the mixture before applying the soap test, due allowance for the dilution being made in calculating the hardness. The so-called temporary hardness of a water may be estimated with an accuracy sufficient for the purpose of guidance in determining the best softening process to be employed by boiling a known volume of the water for about half an hour. After cooling any loss by evaporation is made up with distilled water and 70 cubic centimetres of the filtered water are tested by the soap solution in the ordinary way.

The agents which may be considered to be available for softening processes in laundry practice are heat, lime, caustic soda, carbonate of soda, and mixtures of the last three. With regard to heating as a method of softening water, it is seldom that anything approaching to the amount of water required can be treated by the available sources of heat which would otherwise be wasted, and the direct application of heat is out of the question on the score of expense. Even when waste heat is obtainable in quantity the process is only applicable to water in which the hardness is mainly temporary. In general practice therefore one or more of the three substances mentioned must be adopted, and the principles of applying them should be understood in order to make sure of getting good results with economy.

Lime acts on water which is hard from the presence of calcium and magnesium carbonates dissolved in carbonic acid by combining with this acid to form insoluble calcium carbonate, which is precipitated along with the carbonates which were in solution since they are deprived of the carbonic acid which made them soluble. In this way a water which has only temporary hardness may be softened to a

* Pure sodium oleate is perhaps the best soap to use.

very great extent by adding to it lime either in the form of powdered slaked lime or of lime water. The action expressed in the form of a chemical equation is

$$CaCO_3\,H_2CO_3. + Ca\ (OH)_2 = 2\ CaCO_3 + 2\ H_2O.$$

In practice it is not possible to realise so perfect a reaction as is represented by this equation. A temporarily hard water softened by lime will still show a hardness of about three or four degrees. The best way of applying lime as a softener is undoubtedly in the form of lime water, but as the solubility of slaked lime in water (1 part of $Ca(OH)_2$ in about 700 parts of water) is small, the use of lime water involves storage tanks. It is therefore more usual when lime is used on the small scale to add it in the form of powdered slaked lime, made up into a milk with a little water. By calculation from the equation given above it is found that 100 parts of calcium carbonate dissolved in carbonic acid require 56 parts of quick lime (CaO) or 74 parts of slaked lime ($Ca(OH)_2$) for theoretically complete precipitation. If then the temporary hardness of a water has been determined, it is easy to ascertain the amount of lime which should be added as a first approximation to the best proportions for softening. In making preliminary experiments with lime it is as well to use a fair quantity of water, such for instance as ten gallons. Working on this amount each degree of temporary hardness will require 5·6 grains of quick lime or 7·4 grains of slaked lime. Assuming that a good lime from limestone contains about 90 per cent. of quicklime, the amount of lime on this basis theoretically required for the temporary hardness found should be added to the ten gallons and the water well stirred and left to settle for a few hours. The hardness may then be determined, and if the softening has not been sufficient a further trial with a larger proportion of lime can be made. There are several tests for ascertaining when sufficient lime has been added, but they are all better suited to experiments with lime water rather than with milk of lime, and in actual practice it will be found more satisfactory to rely on the determination of the hardness which will be found to rise again when an excess of lime has been added. With a little practice three experiments should be sufficient, and as they may be all started at once very little time need be spent over the trial. It is of course important to take a fair average sample of the lime to be used.

With most waters more lime will be required than is indicated by the temporary hardness, as there is in nearly all cases a larger amount of carbonic acid present than that which is necessary to hold the carbonates of calcium and magnesium in solution. If a water contains any appreciable amount of magnesium salts, such as chloride or sulphate, the action of lime on them produces magnesium hydroxide, part of which remains dissolved in the water and may be deposited by the action of heat, thus giving rise to trouble with the injector of the boiler. This difficulty may be overcome to a great extent by adding a little sodium bicarbonate to the water after the lime has acted for a short time.

It will be recognised from what has gone before that lime can only deal with temporary hardness. When a water is hard from the presence of calcium sulphate or chloride, the sulphate being the common form, and there is practically little dissolved calcium carbonate, the proper softening agent to use is sodium carbonate, the action of which is represented by the equation—

$$CaSO_4 + Na_2CO_3 = CaCO_3 + Na_2SO_4,$$

that is to say calcium sulphate and sodium carbonate yield insoluble calcium carbonate, while sodium sulphate goes into solution. A calculation shows that each degree of permanent hardness on 10 gallons of water requires 10·6 grains of pure sodium carbonate (Na_2CO_3).

Testing with soap solution will show whether the hardness has been satisfactorily removed, but it will not indicate whether too much sodium carbonate has been added. Excess is to be avoided, as, in addition to being wasteful, it may lead to serious priming in the boiler. In the next lecture the determination of the strength of alkaline solutions will be shortly described, and the method given then may be applied to the present case. When a water has both temporary and permanent hardness, the softening agents to be used are a mixture of lime and sodium carbonate or caustic soda ($NaOH$) by itself, or a mixture of caustic soda and sodium carbonate, or a mixture of lime and caustic soda. Which is best and what proportions of the ingredients of the mixtures are most suitable depend on the nature of the hardness, *i.e.*, on the relative amounts of temporary and permanent hardness. Waters vary also in the character of the deposit given with softening agents, and whether this settles or filters easily, will be found frequently to depend on the nature of the softener used. So far as this particular

point is concerned each water must be treated on its merits, but the general principles guiding the choice and application of softening agents for waters exhibiting mixed hardness, may be described briefly as follows :—

Caustic soda behaves in a similar way to lime with regard to temporary hardness—

$$CaCO_3 . H_2CO_3 + 2 NaOH = Ca CO_3 + Na_2CO_3 + H_2O,$$

but with this difference, that soluble sodium carbonate is formed at the same time. Now as sodium carbonate acts on permanent hardness thus—

$$CaSO_4 + Na_2CO_3 = CaCO_3 + Na_2SO_4,$$

it follows that if the two forms of hardness are in about equal proportions, the addition of an appropriate amount of caustic soda would effect a satisfactory softening. In the case of such a water, each degree of temporary hardness would require for 10 gallons of water 8 grains of caustic soda, and the sodium carbonate produced by the combination of the caustic soda with the carbonic acid which previously held the calcium carbonate in solution would deal with the permanent hardness. But here again it must be remembered that the water will contain some excess of carbonic acid, and a trial must therefore be made to ascertain if further softening can be effected by using a little more caustic soda than the amount which is theoretically indicated. Where the excess of carbonic acid is greater than that with which caustic soda can be considered to deal with economically, it is clear that the addition of some lime along with the caustic soda will save expense. Remembering that 80 parts of caustic soda are equivalent to 56 parts of quick lime, the proper amount of the latter may be calculated and added instead of the extra caustic soda found to be necessary over and above what was indicated as sufficient to deal with the hardness as such. A mixture of lime and carbonate of soda in water becomes calcium carbonate and caustic soda, if the quantities used are in proportion to their chemical equivalents as shown in the equation—

$$CaO. H_2O + Na_2CO_3 = CaCO_3 + 2 NaOH,$$

which indicates that 56 parts of quicklime and 106 parts of pure sodium carbonate yield 80 parts of caustic soda. Such a mixture may be used in the place of caustic soda, but it must be borne in mind that whenever lime is used a bulkier deposit is obtained than by the addition of alkali alone. When the water has to be filtered after softening it may be inconvenient to deal with a large amount of solid matter. When it is desirable to soften a water in which the proportions between the two forms of hardness are not equivalent, a mixture of lime and sodium carbonate, of lime and caustic soda, or of caustic soda and sodium carbonate may be used.

In the case of the temporary exceeding the permanent hardness, lime may be added equivalent to the temporary hardness and then sodium carbonate equivalent to the permanent hardness. Taking as before a volume of 10 gallons of water, the figures are 5·6 grains of quicklime for each degree of temporary hardness, and 10·6 grains of pure sodium carbonate for each degree of permanent hardness. If a mixture of lime and caustic soda is to be used on such a water, add caustic soda equivalent to the permanent hardness, and add lime equivalent to the number of degrees of hardness obtained by subtracting the permanent from the temporary hardness. For 10 gallons each degree of permanent hardness requires 8 grains of caustic soda. Taking as an example a water containing 15 degrees of temporary and 9 degrees of permanent hardness, the proportions used in a trial on 10 gallons were—caustic soda equivalent to 9 degrees of permanent hardness, $9 \times 8 = 72$ grains. Quicklime equivalent to $15 - 9 = 6°$ $5·6 \times 6 = 33·6$ grains. Thirty-four grains of quicklime were actually used and the water was softened to 5·5 degrees. It was not found to be economical to carry the softening below this amount.

When the permanent hardness is in excess of the temporary hardness a mixture of lime and sodium carbonate or one of caustic soda and sodium carbonate may be employed. A mixture of lime and caustic soda is seldom applicable in such a case, as in all probability there would not be sufficient extra carbonic acid present in the water to furnish, with the caustic soda when lime is present in addition, the requisite quantity of sodium carbonate for dealing with the permanent hardness.

Taking again a volume of 10 gallons for a trial experiment and using sodium carbonate and quicklime, 10·6 grains of pure sodium carbonate are added first for each degree of permanent hardness and then 5·6 grains of quicklime for each degree of temporary hardness.

With regard to the use of a mixture of caustic soda and sodium carbonate an experiment should be made first with caustic soda alone, as it may very well happen unless the

permanent hardness exceeds the temporary to a marked extent, that there is carbonic acid enough dissolved in the water to yield the necessary amount of sodium carbonate, and to give a satisfactory softening. If this is not found to be the case, and it is desired to use a mixture of caustic soda and sodium carbonate, a trial may be made in the following way. Add caustic soda equivalent to the temporary hardness and then sodium carbonate equivalent to the number of degrees of hardness obtained by subtracting the temporary from the permanent hardness. As a guide, take a theoretical example of a water containing 16 degrees of permanent and 6 degrees of temporary hardness. For 10 gallons add $6 \times 8 = 48$ grains of caustic soda. This amount, while removing the temporary hardness, will produce sodium carbonate sufficient to deal with 6 degrees of permanent hardness. Therefore more sodium carbonate equivalent to $16 - 6 = 10$ degrees must be now added, or $10 \times 10 \cdot 6 = 106$ grains Na_2CO_3. In actual practice it would most probably be found desirable to use more caustic soda than is indicated so as to take advantage of its formation of sodium carbonate with any extra dissolved carbonic acid, and to decrease the amount of sodium carbonate proportionately. Otherwise there would be the danger of leaving the water alkaline from sodium carbonate and bi-carbonate, with the accompanying objection with regard to its use in boilers.

It has been mentioned above that caustic soda acts on a water containing only temporary hardness in a similar manner to lime, but as sodium carbonate is formed at the same time and remains in solution, the use of caustic soda for softening a water of purely temporary hardness has not been recommended, not on account of any valid objection to such softened water for washing purposes, but because of the danger of priming when the same supply is used also in the boiler. The answer to the question, how far is it desirable to soften a water, must depend to some extent on the use to which the softened water is to be put. No doubt for washing purposes merely the water cannot be too soft, but the cost of removing the hardness almost completely may well exceed the loss due to the waste of soap caused by a moderate degree of hardness. Softening down to between four and six degrees may be considered to be as far as it is practicable to go with due regard to reasonable economy. Such a degree of hardness will eave a water in most cases in a fit condition to be used in a boiler for steam raising. Comparatively little deposit will come out of it, but some precipitate to cover the boiler plates and act as a protective coating is needed ; otherwise there is the danger of corrosion and pitting becoming apparent in the metal at some time or other. There is not time in this lecture to deal in any detail with the nature and causes of pitting, nor, indeed, would it be quite appropriate to do so, but the question of a remedy, should the defect tend to become serious, is of importance to workers in a power laundry; and the practical result of a very large number of experiments carried out at King's College, and extending over some years, may be given briefly in the form of directions for treatment. The quantities mentioned are for 310 gallons of water :—

(1.) Clear out the boiler, and fill up a little above the usual mark with water in which 20 lbs. of silicate of soda (soluble glass) have been dissolved. Boil for four hours or longer.

(2.) Run off when cold, and fill up with water containing 15 lbs. of barium hydrate ($Ba(OH)_2 . 8H_2O$) dissolved in it. Boil for four hours or longer.

(3.) After the boiler has been used for about a week put in 28 lbs. of chalk lime and boil for four hours or longer.

The period of four hours is given as a minimum, the actual time will depend on the convenience of the user of the boiler. It is, however, not advisable to allow more than three or four days to elapse between (1) and (2). Boilers treated in this way and which previously showed serious pitting have been constantly under observation for six years without any return or continuance of the mischief being apparent.

Before leaving the subject of water a very brief reference may be made to the substances used as boiler compositions or "anti-incrustators." Very many of them contain either caustic soda or sodium carbonate, and their use depends on the chemical action between them and the calcium salts in the water giving rise to a loose deposit and preventing the formation of the hard adherent and coherent coating which forms the objectionable scale derived from some waters, and more especially from those which contain calcium sulphate. It is clear that these alkalies should be used in quantities determined by the particular nature of the water, as any excess over and above that amount which is required for the reaction would tend to encourage priming. Sometimes the alkalies are mixed with various waste

organic substances, *e.g.*, sawdust, peat, tan, disintegrated leather clippings, &c. With certain waters the organic matter appears to have some useful action and to assist in preventing the setting of the substances which make up the scale into hard coherent masses. Another kind of boiler composition is to be found which contains ammonium chloride. The object of this is to convert the calcium carbonate into calcium chloride which is very soluble. At the same time, however, ammonium carbonate is formed, and as this is volatile and comes over with the steam it is very likely to produce serious corrosion of any copper or brass fittings. The use, therefore, of such a boiler composition is to be condemned in most cases. Whatever anti-incrustator is chosen, it should be used with a full knowledge of its composition and the nature and extent of its action.

Closely connected with water from a launderer's point of view, and of equal importance, is the subject of soaps. The details of their manufacture is outside the scope of the present lectures. As a rule soap is not made in the laundry but obtained from one of the many manufacturers. There are, however, some laundries in which the soaps required are made successfully, and with economy, and analyses of specimens of such soaps have proved them to be of very good character. There are probably few other materials in the manufacture of which the art of adulteration has been applied so extensively as it has been to soap. There are, however, many good soaps to be obtained of manufacturers of reputation, and it is the object of the remarks which follow to indicate as briefly as possible what constitutes a good soap for laundry purposes, and to give such directions for the application of simple tests as will enable the launderer to form an estimate of the value of soaps offered to him.

Soaps, as ordinarily understood, are either the sodium salts (hard soaps) or potassium salts (soft soaps) of fatty acids of relatively high molecular weight. Resin acids are also used in the manufacture of some soaps. The raw materials from which soaps are manufactured vary considerably, but they are, with the exception of resin, animal or vegetable fats or oils. Chemically they are described as the ethereal salts of glycerine and fatty acids, and the action of the caustic alkalies used to convert them into soaps consists in the production of the salts of the alkalies of the fatty acids of the fats or oils with the accompanying formation of glycerine. Such a change is generally known as an example of "hydrolysis," the term saponification, however, being more generally used to describe the special case of hydrolysis by alkalies at present under consideration. Taking glycerine oleate (generally called glyceryl oleate) as a typical example of an ethereal salt of a fatty nature, and caustic soda as the alkali used to effect its saponification, the reaction may be represented by the equation—

$$\underset{\substack{\text{glyceryl oleate} \\ (884)}}{C_3H_5\,(C_{18}H_{33}O_2)_3} + \underset{(3 \times 40 = 120)}{3\ NaOH} = \underset{\substack{\text{glycerine} \\ (92)}}{C_3H_5\,(OH)_3} + \underset{\substack{\text{sodium oleate} \\ (i.e.\ \text{soap}) \\ (3 \times 304 = 912)}}{3\ (NaC_{18}H_{33}O_2)}$$

The numbers in brackets underneath the names are the molecular weights and multiples of these weights in the case of the caustic soda and sodium oleate, and show the theoretical proportions of the fat and soda used, and of the glycerine and soap obtainable from them.

100 parts of good tallow require about 12·5 parts of caustic soda, and furnish about 103 parts of dry soap.

100 parts of cocoanut oil require about 19 parts of caustic soda and yield about 108 parts of dry soap.

These numbers are not given as anything more than a general guide and as useful to remember in view of the remarkable yields of soap which are sometimes obtained. For example, a mixture of the following nature can be made to furnish a material which will retain the shape given to it and exhibit some of the properties of soap—

100	parts	cocoa-nut oil.
15	,,	palm-nut oil.
75	,,	resin.
255	,,	soda lye (specific gravity 1·28).
250	,,	sodium silicate.
130	,,	filling, *e.g.* chalk, clay, &c.
825	,,	so-called soap.

It would lead too far from the purposes of this lecture to deal with the constitution of the different fats and oils which are worked up into soaps, but the following may be mentioned as examples, together with the names of the principal fatty acids contained in them in the form of ethereal salts of glycerine :—

Fat or oil.	Acids.
Tallow	Stearic, oleic, palmitic.
Olive oil	Oleic, palmitic, linoleic.
Palm oil	Palmitic, oleic (frequently a considerable proportion of the palmitic acid is in the free state).
Cotton-seed oil ..	Oleic, linoleic, stearic, palmitic.
Castor oil	Ricinoleic, stearic.
Cocoa-nut oil .... / Palm-nut oil	Myristic, lauric, palmitic, oleic.

The compounds made by the action of alkalies on a resin such as colophony consist mainly of the sodium salt of an acid of high molecular weight, known as abietic acid. The substances made by the action of alkalies on resins alone are hardly to be called soaps in the general acceptation of the term, but when fats and oils are saponified along with a certain amount of resin true soaps are obtained. The following Table gives the names and formulæ of the chief acids mentioned above, together with the molecular weights of their anhydrides, the weight of sodium oxide (Na_2O) required to convert the anhydrides into sodium salts of the acids and the percentages of alkali (Na_2O) present in the resulting dry soaps:—

Name of acid.	Formula.	Molecular weight of anhydride.	Weight of alkali (Na_2O).	Percentage of Na_2O.
Ricinoleic.	$C_{18}H_{34}O_3$	578	62	10·72
Stearic....	$C_{18}H_{36}O_2$	550	,,	11·27
Oleic	$C_{18}H_{34}O_2$	546	,,	11·37
Linoleic ..	$C_{18}H_{32}O_2$	542	,,	11·42
Palmitic .	$C_{16}H_{32}O_2$	494	,,	12·55
Myristic ..	$C_{14}H_{28}O_2$	438	,,	14·15
Lauric	$C_{12}H_{24}O_2$	382	,,	16·25

The molecular weights of the anhydrides, which are obtained by doubling those of the acids and subtracting the molecular weight of water, viz., 18, are given instead of the molecular weights of the acids themselves, as it is in the form of anhydrides that fatty acids are returned in the analyses of soaps. The reason is seen from the equation—

$$\underset{\text{stearic acid.}}{C_{18}H_{36}O_2} \times NaOH = \underset{\text{soap.}}{NaC_{18}H_{36}O_2} + \underset{\text{water which is eliminated.}}{H_2O}$$

As the alkali is expressed as sodium oxide (Na_2O), then $2(NaC_{18}H_{36}O_2)$ is to be looked upon as a compound of Na_2O, and $\begin{matrix}C_{18}H_{35}O\\C_{18}H_{35}O\end{matrix}\Big\rangle O$, *i.e.*, stearic anhydride. Adding together the numbers for anhydride and Na_2O will at once give the amount of dry soap.

It will be seen from the numbers for percentages of Na_2O given in the Table, that the higher the molecular weights of the acids are the smaller is the percentage of Na_2O present in the soaps made from them. It may be stated as a general rule and without troubling about details of certain exceptions, that experience shows that the soaps of acids of the same series of high molecular weight possess superior lathering properties over those made from acids lower in the series. Oleic acid stands very high in this respect, but in making comparisons the question of solubility must be taken into account, the alkaline salts of oleic acid being among the most soluble of all soaps. The molecular weight of the resin acid, abietic acid ($C_{44}H_{64}O_5$) is very high, and there is no doubt that the use of resin in making soap promotes the lathering properties of the product. This is a convenient opportunity to consider how far the presence of resin is permissible in soaps for laundry purpose. A large number of experiments were made under strictly comparable conditions with many soaps free from resin, and with soaps similar in other respects but containing various proportions of resin, and it was found that it was not a matter of opinion but a fact beyond question that linen and cotton goods repeatedly washed with soap containing resin became markedly more coloured of a yellowish-brown hue than equal portions of the same goods washed in the control experiments with soaps free from resin. The difference was quite noticeable even when the resin acids did not exceed 5 per cent. of the total fatty acids of the soap, and the higher the percentage of resin the more marked was the effect.

From what has been said it will be gathered that a good soap for laundry purposes will consist of the sodium or potassium salts of fatty acids of high molecular weight, a large proportion of these acids being oleic acid, associated with water and practically nothing else. It is clear, however, from the conditions of manufacture, that some small amount of alkali over and above that which is combined with the acids may be present. Glycerine also may form a constituent of soaps in small amounts only when its separation is part of the process of manufacture, and will be present in appreciable quantities when, as in the case of many soft soaps, no attempt is made to remove it. It is an advantage to any one engaged in conducting or directing the technical processes of modern laundry work to be able to carry out

such simple tests and experiments as will serve to make an estimate of the value of the materials employed. The tests and analytical methods connected with soaps which are to be described now as briefly as possible are not intended to be in any way complete or exhaustive. As a rule the launderer is not concerned with minute details but rather desires to ascertain the general value and order of purity of the soap supplied to him. His own experience is sufficient guide as to its efficiency. It is more with a view to criticising new and possibly better articles that he may wish to be able to apply tests which will give him some data to go upon before making an experiment with them on the large scale.

First, as regards the possible presence of resin. The simplest way of testing for this substance is to decompose a small quantity of the soap, say about 5 grams, by boiling it with water to which enough dilute sulphuric acid has been added to render the liquid distinctly acid, that is so that it reddens blue litmus paper freely throughout the process. The fatty acids will be set free and will float as an oily layer upon the watery solution. When the change is seen to be complete by the transparency and fluidity of the oily layer, the whole mixture is to be cooled until the fatty acids solidify, as they will in the case of all soaps except those which are unusually rich in alkaline oleates. A small portion, about the size of a pea, of the fatty acids separated and dried is then to be dissolved in about two cubic centimetres of acetic anhydride (not to be confused with anhydrous or glacial acetic acid) the solution being helped by gentle heat. After cooling this solution thoroughly, two or three drops of a cold mixture of equal volumes of glacial acetic acid and strong sulphuric acid are added, and if resin acids are present an unmistakeable violet colour will be produced. The colour is fugitive, but by keeping the solution cold and using the mixture of glacial acetic acid and strong sulphuric acid instead of sulphuric acid alone, it is possible with care and experience, and by taking precautions to conduct the experiment always in the same way and with the same quantities, and to operate on fairly weak solutions of the fatty acids, to form a rough judgment by means of this test of the relative amounts of resin by estimation of the depth of colour compared with that given by a soap containing a known amount of resin acids. In all soaps which are ever likely to be met with the only substance other than resin which will give a similar colour is cholesterol from wool fat. This may be eliminated by shaking a solution of the soap, before decomposing with sulphuric acid, with ether or petroleum ether, either of which will extract the cholesterol. The percentage of fatty acids present in a soap can be readily determined with moderate accuracy by decomposing 10 grams of soap with dilute sulphuric acid in the same way as has been just described. The cooled and solidified cake is separated, melted, and dried, and its weight determined when cold. Should the fatty acids be found to remain liquid or inconveniently pasty on cooling, the difficulty can be overcome by adding a known weight, about 5 grams, of beeswax or stearic acid to the mixture of soap and sulphuric acid, so that it may incorporate thoroughly with the fatty acids, and by its higher melting point confer solidity on them. The weight of added matter is of course allowed for in the determination. When this process is being carried out any filling of an insoluble nature such as talc, silicates, &c., will be revealed by a white precipitate settling on the bottom of the vessel.

An easy and simple method of forming an estimate of the amount of fatty acids contained in a soap is to use the standard calcium chloride solution described under the determination of the hardness of water. A solution of the soap in question is made up in the proportions of 10 grams to a litre of weak alcohol, and used with the calcium solution in the manner explained for the valuation of the standard soap solution. Assuming that this standard solution was made from a soap of acknowledged purity and high fatty acid content, the relative value of any other soap can in this manner be ascertained quickly and with fair accuracy.

The amount of water in a soap can be found with fair accuracy by heating 5 grams in a vessel such as a porcelain dish or crucible large enough to allow of the soap being stirred freely with a glass rod which has been weighed along with the vessel. The heating is continued until a cold watch-glass, or failing that, a plate of glass laid on the vessel from time to time ceases to be dimmed by moisture. An argand gas burner turned down very low is a convenient source of heat; but, whatever is used, care must be taken not to burn the soap. The loss of water is determined by weighing after the vessel and its contents have become quite cold. The total alkali in a soap consists of the alkali combined with the fatty acids and

of that which is present either as free caustic soda or potash or as sodium or potassium carbonates, and sometimes borates and silicates. In the process described above of separating the fatty acids by boiling with dilute sulphuric acid, the total alkali of the soap combines with and neutralises a part of the sulphuric acid. If, then, the strength and volume of this acid used are known, and a determination by means of an alkaline solution of known value is made of the excess of free sulphuric acid, left after all the soap has been decomposed, a simple calculation will give the amount of total alkali present in the soap. The two processes of determining the fatty acids may thus be combined together, but it is generally more convenient to take a smaller weight such as 4 grams of soap for the total alkali, and to make the determination separately. For the details of preparing and using standardised acid and alkaline solutions reference is made to the next lecture under alkalies used in laundry work.

The presence of alkali other than that combined with fatty acids may be shown and determined in the following way. A weighed quantity of the soap such as 4 grams in fine shavings is dissolved in boiling alcohol which should be of not less than 90 per cent. strength. Methylated spirit can be used if it has been left for some time in contact with lumps of good quicklime in a stoppered bottle. It should be filtered before use. If the soap is one containing very much water it should be gently heated, without melting, after it has been weighed, so as to expel the greater part of the water. The soap and any free caustic alkali dissolve in the alcohol leaving the alkaline carbonates, borates or silicates as an insoluble residue mixed with any filling, common salt, &c., which may be present in the soap. The hot alcoholic solution is filtered, and the residue on the filter is washed free from soap with successive portions of fresh hot alcohol. Roughly speaking, the total amount of alcohol required for the whole process will be about 5 fluid ozs. (150 cubic centimetres). The residue is treated on the filter with distilled water until the soluble alkaline carbonates have been washed through. Their amount can then be determined by finding the quantity of acid of known strength required to neutralise them. As the alkaline carbonates are the only form of alkali likely to be met with in the residue insoluble in alcohol, so far as ordinary soaps for laundry work are concerned, there is no occasion to deal with the question of the separation and estimation of borates and silicates, which would involve analytical processes beyond the scope of the present lecture. Practice and experience will make it quite possible to determine the alkaline carbonate on a smaller quantity of soap than that mentioned with sufficient accuracy for most purposes. Indeed, after considerable acquaintance with the appearance of solutions in alcohol of soaps containing varying amounts of alkaline carbonate, it is by no means difficult to form a very fair judgment of the quantity present by dissolving half a gram of soap in 10 cubic centimetres of hot alcohol in a test tube, and noting the extent of the turbidity. This, of course, only applies to straightforward soaps, in which there is no reason to suspect the presence of any filling, salts, or matter other than alkaline carbonate insoluble in alcohol.

Except in the case of some soft soaps freshly prepared, it is not usual to find free caustic alkali in soap supplied for laundry work. Should any be present it will be found, as has been stated, in the alcoholic solution along with the soap. It can be tested for by adding a drop or two of an alcoholic solution of phenolphthalein, a substance which will give a strong red colour with the alkali. The amount of caustic alkali, if any is found, can be determined by cautiously adding acid of known strength, and noting the amount used to make the red colour disappear. It will sometimes be found that, instead of the alcoholic solution of soap after it has been filtered from alkaline carbonate being alkaline, it is, on the contrary, slightly acid. This is due to the presence of acid steareates, oleates, &c., or to fatty acids. Except in badly-made soaps, the extent of this acidity will be but small, and need not be considered.

Unsaponified fat and unsaponified waxes or oils are very seldom met with in soaps such as are being considered. Should, however, the behaviour of a soap give the launderer any reason to suspect their presence, they may be found in the following manner. About 5 grams of the soap are dissolved in distilled water, and if the solution does not give a red colour with a drop or two of phenolphthalein a little caustic soda or potash is added until it does so. The object of this is to neutralise any free fatty acids which might be present, and which would dissolve in the ether which is to be used for extracting the unsaponified fats. The cold soap solution is then shaken up with ether and the ethereal layer is separated from the lower aqueous layer. The

ethereal solution is washed by shaking it up with about its own volume of water to remove the small amount of soap which dissolves when a moderately strong solution of it is shaken with ether. After again separating the two layers, the ether is evaporated in a suitable vessel over hot water, when the unsaponified fat or unsaponifiable oils will be left, and can, if necessary, be weighed. The amount of ether to be used need not be greater than that which will give a manageable separate layer after shaking up with the soap solution, the volume of which will necessarily be governed to a great extent by the solubility of the particular soap in cold water. The following table of results will give a fair idea of the proportion of the chief ingredients which may reasonably be expected in soaps intended for use in a laundry. The percentages are from analyses made of soaps either used recently in laundries or offered for use. Some details have been omitted to avoid unnecessary complication, and only the main constituents are mentioned. Glycerine, although separately determined, has been included with water, and the insoluble matter mentioned was, in most cases, insignificant in amount :—

	Oil Soaps.		Mottled Soaps.		
Fatty anhydrides	59·65	66·1	63·24	69·50	70·50
Combined alkali (Na_2O)	7·75	7·65	8·48	9·25	9·50
Free alkali (Na_2CO_3) ..	0·31	1·64	0·40	0·45	trace
Water and insoluble matter	32·29	24·61	27·88	20·80	20·00

All of these soaps may be considered to be of good average quality and it will be seen that with one exception the amount of free alkali reckoned as sodium carbonate is low. An average of not more than 0·5 per cent. is what may reasonably be expected in an ordinary laundry soap. It may be said that as additional alkali is often used there is no harm in having a larger percentage of it in the soap, but it is clear that it is far better to be able to add what is wanted separately, and to be sure of a soap which can be used when alkali might be injurious, to say nothing of the difference in cost between sodium carbonate and soap. The last soap strongly resembled old mottled soaps of good quality. At one time mottling was a guarantee of fair dryness in a soap since the segregation of the dirt into lines as the soap cooled and solidified was not possible, if the amount of water exceeded 20 per cent. Mottling is, however, no evidence of absence of excess of water at the present time as the addition of sodium silicate among other things prevents the too rapid settling of dirt or added coloured matter, and makes it possible to obtain a mottled appearance with a high percentage of water. A comparison of a very fair unmottled and a recent mottled soap will illustrate this.

	Unmottled soap.	Poor mottled soap.
Fatty anhydrides	66·25	42·41
Combined alkali (Na_2O)	8·34	4·57
Free alkali as Na_3Co_2, and as sodium silicate	0·42	2·23
Silica	none	1·56
Sodium chloride............	0·13	1·24
Sodium sulphate............	trace	0·53
Water and insoluble matter..	24·86	47·46
Percentage of true soap	74·59	46·98

The worst soap which has yet been examined, and which was offered as a good and economical washing soap for laundry purposes, had the following general constitution :—

True soap	16·03 per cent.
Sodum carbonate and silicate ..	19·24 ,, ,,
Sodium chloride and sulphate..	5·43 ,, ,,
Water and dirt	59·30 ,, ,,

It is, perhaps, needless to comment on such a soap as this, but the fact that it could be actually recommended emphasises the necessity of a general knowledge of the methods of testing soap on the part of the launderer, not only for his own protection, but that justice may be done to the many honest soaps which are manufactured for his use.

Soft soaps are frequently made in the laundry, and in most cases with very satisfactory results. As these soaps are often used for washing woollen goods, it is important that they should contain as small an amount as possible of free caustic alkali, the presence of which in any appreciable quantity would seriously damage the fibre. When soft soap is exposed to the air for some time most of the caustic alkali which might have been present at first would become converted into carbonate by the action of carbonic acid in the atmosphere. A comparison of the percentages of the main ingredients in a sample of fresh soft soap made in a laundry, and in a sample of a commercial article made some time ago, will illustrate this, and will give a general idea of the constitution of a soft soap :—

	Fresh soft soap.		Older soft soap.
Fatty anhydrides	54·62	..	43·50
Combined alkali as K_2O....	9·21	..	8·35
Free caustic alkali as KOH	0·62	..	trace
Free alkali as K_2CO_3	0·30	..	1·74
Water and glycerine	35·25	..	46·41

The glycerine, although separately determined, is given here with the water to avoid unnecessary detail.

A brief reference may be made to soap powders. They are, as a rule, mixtures of some soap with varying proportions of alkali in the form of carbonates associated sometimes with alkaline silicates or borates, and are offered to the launderer as efficient and economical substitutes for the soap and alkali which he is in the habit of using. In view of the price charged for many which have been examined, and of the constitution of them revealed by analysis, it is difficult to see how any advantage can accrue to him by their use. The following analyses of three soap powders will make this evident. Two are very similar in composition, while the third is a mere pretence so far as soap is concerned :—

	A	B	C
Fatty anhydrides	22·12	19·73	2·76
Combined alkali (Na_2O)	3·68	3·26	0·42
Sodium carbonate	28·09	27·52	23·14
Sodium chloride	0·32	1·33	1·75
Sodium silicate........	none	trace	12·64
Sodium sulphate	0·12	0·31	5·37
Insoluble residue	3·80	5·58	8·15
Water	41·87	42·27	45·77

There is nothing in A and B which cannot be better applied in the form of separate ingredients, with the advantage that the useless insoluble matter can be left out. No criticism of C is needed.

In the third lecture the action of soap as a detergent will be specially considered, along with some of its properties, which have been necessarily omitted here.

INSANITY.

The figures to be found in the sixty-first report of the Commissioners in Lunacy, would seem to show that insanity is largely on the increase in England and Wales. On the 1st January, 1907, the total number of notified insane persons in England and Wales stood to the estimated population in the proportion of 1 to 282, or 35·48 per 10,000. This gives an increase on the ratio of the preceding year of 0·48 per cent., whilst the actual numerical increase has been 1·64 per cent. On the 1st January, 1897, this ratio was 31·89, so that in the ten years it has increased by 11·3 per cent., the proportion of such insane persons in the whole community having risen from 1 to 314 to 1 to 282. The actual increase in the whole population during the same period was 12·1 per cent., and in the numbers of the certified insane 24·8 per cent. Calculating the admission rate per annum on 10,000 of population, it will be found that in the year 1869 this was 4·71, in 1902 this ratio was higher than that of 1869 by 47·1 per cent., and in 1906 by 34·0 per cent. From 1869 to 1906 the population of England and Wales increased by 55·5 per cent., the total (known) insane by 133 per cent. The admissions which in 1869 were 10,472, rose to 21,812 in 1906, an increase of 108·2 per cent. But the ratio of insane to population which, on 1st January, 1869, was 23·93 per 10,000, had risen to 35·48 on the 1st January, 1907—an increase of 48·2 per cent.

It has been authoritatively stated that the "only proper test of the increase of mental disease is the proportion of first attacks to the population during different periods." If the figures bearing on this point given by the Commissioners are taken, and the test accepted, the conclusion suggested by the figures given above as to the increase of insanity would appear to be confirmed. The statistics of institutions for the insane afford opportunity for an estimate of the proportion of "first attacks." From a study of the annual averages calculated on the figures of each of the six quinquennial divisions into which this term is divisible, and contrasting the total annual admissions with the totals of ascertained first attacks of insanity, it would appear that the latter have increased absolutely and relatively (to population) to a greater extent than the former. Thus the quinquennial average of male admissions has risen from 6,449 to 10,741, and of females from 6,653 to 11,179 in the years 1876-80 and 1901-5 respectively, giving a rate of increase for males of 66·5 per cent., and for females of 68·0 per cent. As regards these first attacks of insanity, the increase for males has been 75·7 and for females 71·9 per cent. in the like period. If the ratios from 10,000 of the population be taken the result is as follows :—

Ratio per 10,000 of Population of the Annual Average.

	1876-80.		1891-95.		1901-05.
Males—					
Admissions....	5·29	....	5·91	....	6·65
First Attacks ..	3·48	....	4·01	....	4·62
Females—					
Admissions....	5·17	....	5·88	....	6·48
First Attacks ..	3·36	....	3·87	....	4·31

It is only during the past decade that any marked preponderance of cases admitted with their first attack of insanity has occurred. Whilst contrasting the first of the six quinquenniums with the last, it will

be seen that whilst the ratio of total admissions has risen, for males 25·7 per cent., and for females 25·3 per cent., the ratio of "first attacks" has increased by 32·7 per cent. in the case of males, and 28·2 per cent. in that of females. But the Commissioners point out that there are factors to be considered which render it impossible to determine whether the actual proportion of "occurring" insanity is really increasing in the community, and if it be so to what extent. It is probable that far more care is taken to segregate persons suffering from the milder forms of insanity than used to be the case, fitness for detention being considered to imply the need for treatment of a disease quite as much as the fact that the insane person requires protection from himself, or that the community has to be protected from him; and, again, in the case of the aged, whose numbers go to swell the list of "first attacks," removal to asylums is well known to be on the increase. Hence it happens that without any marked increase in the prevalence of mental disorder many such defectives are now being notified who a generation or two ago would have been left outside the pale of official recognition. Such statistics, then, as are alone obtainable, which seem to point to an increase of insanity in the community, are too open to qualification to justify such a conclusion. They deal only with those who have been certified as insane and proper subjects for detention, and their numbers from year to year are influenced by factors the extent of which cannot be estimated. Lastly, the rise in proportion of the numbers of "first attack" cases encourages the belief that the early treatment of the insane is more fully carried out than in former days; whilst the corresponding diminution of *not* first attacks points to the efficacy of such treatment in preventing recurrence of the disorder.

In the fifty-ninth report of the Commissioners attention was drawn to the fact—which must be obvious from a study of the recovery rates of the insane—that there is a constant and considerable flux of patients into and out of asylums. (See *Journal*, October 27th, 1905.) But the material at the disposal of the Commissioners did not permit of any detailed analysis in respect to the proportions who had been discharged on recovery, or removal by death. The Commissioners in their present report attempt such analysis by utilising for this purpose an instructive Table printed in the annual reports of the majority of the county and borough asylums. The Table gives, on the one hand, the numbers admitted in each year from the opening of the asylum, separating the re-admissions; and, on the other, the number of those so admitted who, up to the close of the year of the report, had been discharged "recovered," "relieved," and "not improved;" those who had died during the same period; and finally those who still remained under treatment. The figures of 43 asylums were taken over a period of 20 years—1886 to 1905—with the object of showing what changes occurred in the distribution of those of their inmates who were admitted at periods of 20, 15, 10, 5, and within one year. Taking only the 8009 patients admitted into these 43 asylums during the year 1886, and tracing their fate in successive years up to the end of 1905, we have the following percentages:—

Of each 100 *admissions in* 1886.

	Dis-charg'd.	Died.	Re-mained.
To the end of 1886 (within 1 year)	25·0	10·0	65·0
" " 1887 (" 2 years)	42·4	17·0	40·0
" " 1888 (" 3 ")	47·0	22·0	31·0
" " 1889 (" 4 ")	50·3	24·2	25·5
" " 1890 (" 5 ")	51·8	26·4	21·8
" " 1895 (" 10 ")	55·2	31·0	13·8
" " 1905 (" 20 ")	57·7	36·1	0·2

It will be observed that by far the majority who were discharged recovered left the asylums within two years of being admitted.

THE SCHOLARSHIP SYSTEM AT OXFORD AND CAMBRIDGE.*

The present system of open scholarships at the older universities owes its existence to Richard Jenkyns, Master of Balliol, 1819-1854. Until about eighty years ago help was given to students in two ways. There were scholarships, confined to particular schools, districts, or families, and there were servitorships or sizarships, the holders of which did not necessarily possess very high intellectual qualifications, but who were essentially poor men. Jenkyns's system was the offering of scholarships, after a competitive examination, to school boys without any reference to the question as to whether the money was or was not needed for their university education. The status of scholars was improved, and they were made to rank in the college immediately after the fellows. In a short time many of the most brilliant boys in public schools were attracted to the universities, and what was more important, there was an improvement in the work of the schools, which benefited not only the prospective scholars, but also the rank and file of the school. The competition for open scholarships is perhaps keener in our own day than it has ever been, and the success of a school is now guaged, quite wrongly in my opinion, by the number of open scholarships it can claim at the end of the school year.

It has been several times suggested during the last few years that the scholarship system involves a great waste of money, and schemes have been proposed which, while retaining the stimulus of competition, give the money only where it is needed. This seems the only logical position, and were the question as simple as it sounds few would hesitate to adopt one or other of the solutions. The most recent of these proposals is briefly this, that all entrance scholarships

* Abstract of a paper by Dr. H. B. Baker, F.R.S., read before Section L of the British Association Meeting, at Leicester.

should be of the value of £40 a year, and that they should only be increased when the parent could prove that the increase was necessary. On the face of it the proposal seems reasonable, with the one exception that the giving of £40 a year to a scholar who does not need it seems a half-hearted measure.

Exaggerated statements of the waste of money given in scholarships are so often made that an attempt to arrive at an approximation to the facts should be of interest. The heads of all colleges at Oxford and Cambridge were asked to give an estimate of the proportion of their scholars during the last ten years who could have afforded to reside at the university without the aid of their emoluments. Acknowledgment is gratefully made of the kindness of these gentlemen and of the tutors of colleges in compiling the statistics which it is now possible to bring before the Section. The estimates show that at Cambridge 17 per cent. of scholars could have resided at the university without their scholarships, while at Oxford the proportion is only 6 per cent. But even in many of these few cases it was very largely the opinion of my correspondents that the money given in scholarships was not misused. The head of the college at Oxford which had apparently the largest percentage of wealthy scholars, pointed out that they were largely sons of professional men whose incomes are uncertain. In these cases if the father happens to die during his son's university career there is no possibility of the boy's education being completed without external aid. Many have pointed out the difficulty in dealing with the figures supplied by parents with the object of proving poverty. Others consider that if scholarships were made purely eleemosynary the status of scholars would immediately fall, and a condition of things spring up which exists, to their great detriment, in some of the American universities. It must be remembered that the social life of the older universities is one of the most important things to a youth, and anything which would tend to diminish its educational value is much to be deprecated. Considering the disadvantages which the new scheme presents, I would advocate two alternatives. First, let there be a voluntary relinquishment of the emoluments of a scholarship by a wealthy parent, the other privileges of the scholar being retained. It would soon become a point of honour for a wealthy man to refuse to accept money which would be so useful to poor men. Second, let a former scholar who has attained in later life to a position of comparative opulence, pay back his scholarships in some way or other for the help of other poor scholars. With regard to the first of these proposals, I may point out that it is occasionally carried into effect. At one Oxford college six out of twelve wealthy scholars have during the last ten years refused the emoluments of their scholarships, and isolated instances have occurred at other colleges. With regard to the second proposal, *cum veniret ad pinguiorem fortunam* (when a man has attained to fatter fortune), as the St. Andrews statute has it, he should pay back the money which was the foundation of his fortune. This also is done, and perhaps more often than is known. Occasionally the whole sum is paid back to a college, but more frequently the former scholar, out of the not very fat fortune of a schoolmaster or college tutor, pays the sum back in helping poor scholars at the university.

Either of these systems of relieving college funds would, if backed by the force of public opinion, relieve an amount of hardship and poverty which is scarcely realised by any who have not been either poor scholars themselves or been brought into intimate contact with them. The cost of living varies very greatly at different colleges. It is possible to live with economy at many colleges on £120 a year. Two of my own pupils at Christ Church have managed with self-denial to limit their expenses to £110 a year. Since an open scholarship is £80 a year, and school-leaving exhibitions may give a man another £20 a year, it is not difficult to see that the very poor man has still need of assistance. Most colleges have an exhibition fund from which grants are privately made to the poorest students, and anyone who is willing to pay back his scholarship by the help of which, it may be, he has attained a good position, could hardly do better than contribute the money to such a fund.

JAPAN'S TEXTILE MACHINERY.

At present Japan is a better field for the sale of machinery needed to make finished products than for the manufactured products themselves. In no line of business is this truer than in cotton manufacturing. Japan is straining every nerve to change from a consuming to a producing nation, and it is expected that a great amount of money will be put into textile machinery in the next few years. The tendency of all the mills is to add looms and make cloth for the export trade. The great market for cloth of the kind that can readily be made by Japan in Manchuria and Corea has stimulated the weaving mills, while the yarn business has to withstand severe competition in China with Indian yarn. Many Japanese yarn mills are considering the question of changing to weaving mills, and several have recently done so. The textile machinery market is dominated by British manufacturers to an even larger degree than the textile market. The first mill in Japan that was a success, had English machinery, and the other mills followed. Machinery from Oldham, Blackburn, Burnley, &c., is found in all the Japanese mills, but very little American. According to a recent report of a special agent of the United States Government, there is some prejudice against American textile machinery as being too high in price and too light in construction. Notwithstanding his dexterity in certain lines of manufacture, the average Japanese is a very rough workman, and the managers, therefore, prefer heavy machinery from England to the American article.

The textile machinery imports are increasing rapidly. In 1905 the value of cotton printing machinery brought into Japan amounted to £2,230, of cotton spinning machinery £122,820, and of cotton weaving machinery £38,660. There are several new factories being projected, and established mills are being enlarged, so that if the question of raising more revenue is settled by the Diet without burdening manufacturing industries too much, there will probably be between 50,000 and 100,000 new spindles installed during the year 1907. The Kanegafuchi Spinning Company, whose head office is at Kobe, intend to send their superintendent to England to select machinery for a large saw mill they have decided to erect at Harima, and which they intend to make a model mill. A new mill, to be known as the Oriental, is to be shortly established near Amagasaki, for weaving calico. The proposed equipment is 500 looms, 20,000 spindles for No. 42 yarn, and 10,000 spindles for finer yarn. The Fuhushima mill at Osaka has decided to add 20,000 spindles, so as to increase its yarn production for shipment to China. Several other mills are now being organised, and others are ordering additional machinery. It is by means of exhibitions showing the manufactured products of Japan, held by business men, and encouraged by the Government, that the country is being steadily pushed forward into the line of manufacturing nations, and the Gonikai Exhibition, which has recently been held, showed great diversity of manufactures. The leading lines exhibited were textiles, silk yarn and silk cloth, cotton yarn and cotton piece goods, blankets of all kinds, both woollen and cotton, and hand and machine-made matting. There was also an important exhibit of rugs made with cotton warp and rice straw filling. Also many cotton carpets. The great majority of the cotton piece goods were prints put up in bolts about fifteen inches wide, and about thirteen yards long. The goods were for sale, as well as for exhibition. Each bolt was put up in an attractive manner, and a large number of them had silk thread attached for use in making up the garments. A good many pieces are sold rolled, instead of folded. One Japanese cotton mill, the Tsushima Spinning Company, in Owari Province, in Central Japan, has 100 looms working on fifteen inch print cloth, but the majority of the immense quantities of narrow prints made, and used so extensively for *kimonos*, are made on hand looms. The price is from twopence farthing to threepence halfpenny per yard. In addition to the narrow cotton prints, which were the main exhibits of cotton piece goods, there were also interesting exhibits of the goods made in the mills in Japan, composing mostly grey sheetings, drills, cotton crape and cotton flannel, also some duck, and shirtings, and twills. One of the most interesting sights at the Gonikai Exhibition consisted of the three new Japanese invented looms, and as showing what Japan is doing in the way of invention, they were of importance. They are inferior to the British, and also to the American looms, but they are ingenious, and serve to illustrate the growing determination of the Japanese to strike out along new lines, and to manufacture their own textile machinery as well as their own textiles. What first strikes the observer is the amount of wood used. The frames of all three were of wood, and wood s used wherever practicable, such as loom beam heads, whip rolls, levers, shuttle boxes, &c. The largest loom was labelled "The one Tsuda system Habutai Power Loom," and was made by the Matsuwo Works, Azabuku, Tokyo. It is used for weaving the transparent "habutai," about thirty-six inches in width. Except for the wood used, and modifications in details, this loom is not important.

The next loom is for weaving silk or cotton cloth, about twenty-four inches wide, and is notable for its method of harness raising for its stop motion, and also for being self-contained—that is, no driving belts, pullies, gears, or levers being outside the framework. The driven pulley is under the loom at the middle of the cam shaft, and is belted from below, and belt shifted by foot lever at front of the loom. There are no cams, treadles, or strapping used to work the harness. The two harnesses used have wooden ends, and slide in grooves in the frame work. To the centre of each heddle frame end is fastened a curved iron rod, the other end of which is attached to a short set-screwed crank arm on the cam shaft. As the cam-shaft revolves this crank arm through this rod imparts a reciprocal up and down motion to the harness, and by means of the set-screwed arm their motion relative to each other, and to the lay, can be adjusted. The width of shed can be regulated by changing length of rod where it joins the crank arm. The picking motion is also peculiar. While the picker stick is thrown with cams, levers, and lug straps in the usual way, the picker stick proper is under the loom, and half the usual length. It is of wood, but at the top there is hinged by means of a screw an iron rod that runs out horizontally, and curves up into the shuttle box, and the end of this rod carries the picker firmly attached. With this arrangement, owing to the hinge construction, the picker moves in a straight line. This loom also has an ingenious warp-stop motion attachment operating through the heddles. The third loom is used for weaving the narrow print cloth that is usually made about thirteen and a half inches wide. It shows more points of dissimilarity from the usual styles, and so is of more interest than the others. No lug straps are used, but the power is applied to the picker stick by means of a lever striking a casting on foot of picker stick. The foot of the picker stick is bolted into a casting that is pivotted on a horizontal bolt from another casting on the end of the sword rock shaft. A wooden lever is pivotted at the back of the loom on the side, and its front end rests on the projecting casting attached to the foot of the picker stick. An iron piece with projection is bolted to the middle of this lever. The end of cam shaft projects beyond the loom, and carries a free roller on the

crank pin of a short crank arm set-screwed on the end of the cam shaft. As the cam shaft revolves, the roller is carried round and strikes the casting on the lever, which is forced down and strikes the projection on the pivotted casting carrying the picker stick, thus causing the loom to picker. The picker stick is brought back into position by a spring arrangement. The picker is loose on the end of the picker stick, and kept in position by the sides and top of the wooden shuttle boxes. This picking motion is patterned after a common English make, but is modified. The shuttle boxes being made of wood, there is no binder used to check the shuttle and prevent rebounding. The checking is accomplished by two loops of leather, one inside the other fastened with thumbscrew to projection under the end of the lay. The last two looms were made by the Toyoda Shokai Company at Nagoya. The company made in all four styles of looms, viz., (1) The wide loom for thirty to thirty-six inch cloth with iron frame: this loom has not been a success, and fifty of them tried at the Kanegafuchi Mills are to be replaced by English looms; (2) the narrow loom with iron frame; (3) the narrow loom with wood frame; and (4) the narrow loom with wood frame and automatic stop motion. The third is the most popular, and it is said that about three hundred a month are being turned out, the majority of them going to small hand and power loom establishments scattered throughout the Empire.

YUCATAN FIBRES.

Sisal grass or hemp, henequin, or simply sisal, are the various commercial terms applied to a fibre that is neither a grass nor a hemp. The term "sisal" was applied to it because it originally reached the outer world through the Yucatan port of that name. The agave, according to the American Consul at Progreso, is one of the most characteristic plants of Mexico. One species produces pulque, the intoxicating drink of the country. Great fields of this plant are found upon the table lands, and long pulque trains are run daily into Mexico city. The *Agave sisalensis*, another species, furnishes a fibre capable of binding wheat. There are four varieties of this plant growing wild in the forests of Yucatan —the chelm, cahum, pabci, and the citamci. There are also two varieties of the cultivated plant—the yaxci or green fibre, and the sacci, or white fibre. The last-named is the most largely cultivated and the one producing the sisal hemp of commerce. The fibre-cleaning machines in use in Yucatan, in order of precedence by priority of invention, consist of what are called the pacché, the tonkas, and the raspador. The pacché is a triangular, sharp-edged piece of wood, with rounded ends as handles. A wood log with a flat face is made with a hole and a peg in the upper portion. One end of the leaf of the plant is firmly fixed in the flat surface by jamming it into the hole and pushing the plug in after it; then the pulp is scraped away, leaving the fibre hanging from the uncleaned half of the leaf. The leaf is then reversed, the clean fibre fixed into the hole, and the uncleaned portion made ready for the action of the cleaner. The tonkas is a flattened piece of hard wood, about eighteen inches long by five inches wide. At the upper end it is about one inch thick, and it dwindles until at end it becomes a thin, sharp edge, curving inward, so as to grip and save the pulp from the fibre. The bed-board of the tonkas has a curve to coreespond with the curve in the edge of the implement. The leaf is placed between the bed-piece and the tonkas, and while the tonkas is held firmly in one hand, the other draws the leaf towards the body, this movement being repeated until one-half of the leaf is clean. The same operation takes place on the second half of the leaf. The pacché is the implement most in use to-day among the natives of the interior of Yucatan, and with which one person can produce from six to nine pounds of fibre daily. The next step in the evolution of the fibre-cleaning machine is the raspador, which in principle is a wheel upon which are placed the edges of many pacchés. With the aid of this machine two men can clean in one day more than forty men are able to accomplish with the tonkas and pacchés. There are many other labour-saving devices, some of them proving very effective. The total output of sisal hemp from Yucatan during the year 1906, was 600,000 bales, weighing 214 million pounds, and having a value of £2,700,000.

ROADS IN YUNNAN.

In his report on the trade of Mentgtzu just issued (Cd. 3727-15) Mr. Consul-General Wilkinson refers to the great want of roads in Yunnan province. Except for the stretch between Laokai and Manhao (both in the Red River) and a few miles across the larger lakes, there is no water carriage in Yunnan. Everything has to be carried on the backs of men, mules, ponies, or bullocks. A mint has lately been erected at Yunnan, and machinery reached Laokai several months before the date of the Consul-General's report. The machinery was brought to Laokai by rail from Haiphong, then placed on board junks which sailed or were towed up the river to Manhao. Thence each heavier section was being painfully hauled on a crude waggon by gangs of 20 to 30 men over the most appalling of roads, the main route mounting 6,000 feet in the first two or three miles. Nowhere in China, except, perhaps, in the sister province of Kueichow, are railways, or the construction and upkeep of properly graded roads, more needed. In their absence the wear and tear on man, beast, and package continues to the inevitable dislodgement of trade. The only scientific improvements so far essayed in Yunnan are the French railway now being built from Laokai on the Tongking frontier to Yunnanfu, and the continuation to Manhsien of the carriage road between Bhamo, on the Irrawadi and the Kulikha.

HOME INDUSTRIES.

Ventilation in Coal Mines.—The Government have appointed an expert mining engineer to investigate and report on the conditions of ventilation prevailing in coal mines in the United Kingdom. The appointment is the direct outcome of the report of the Royal Commission on Mines. It is not in dispute that much remains to be done in the matter of the better ventilation of mines. Inspectors complain that the language of the Act puts them at disadvantage when prosecuting the owners of ill-ventilated mines, owing to the vagueness of the legal definition of "adequate ventilation." What is adequate ventilation? Proper ventilation in a coal mine is a much more difficult matter than in a factory. In the latter, when an adequate system of ventilation is laid down it suffices until there is extension or re-building, but in a coal mine the conditions are constantly changed, and varying quantities of air are required in different parts of the mine as the position of the workings are altered. Leakage of air into old workings is another difficulty. There is need for more accurate marking of all ventilation currents on the colliery plans, and the driving of air-crossings in the solid rock as a safeguard against short circuiting of the air supply after explosions or subsidencies. These and other points will, no doubt, be reported on by the expert who has been appointed by the Government, and it may be hoped that his investigations will result in measures being taken to rectify admitted shortcomings in the ventilation systems of coal mines.

Wheat Supplies.—It is many years since the British farmer was so favourably placed in respect to his wheat crop. Speaking generally there has been an average crop, splendidly harvested, and commanding prices higher than any of recent years, with the prospect of much higher quotations for those who can afford to hold until the winter. During the past week there has been a further advance of from 2s. 6d. to 3s. 6d. per quarter. Wheat is now over 40s. per quarter, and owes nothing of the enhanced price to market manipulations. A study of the position warrants the conclusion that there will be further and even larger advances in price. The wants of the importing countries this season may be put at about 72,500,000 qrs.; the maximum prospective supplies do not exceed 65,000,000 qrs. The October report of the Washington Bureau may be taken as indicating the actual results of the crops in America, and it shows that whilst in 1905 the yield of wheat was, roughly, 700,000,000 bushels, and in 1906 735,000,000, in 1907 it is only 625,000,000 bushels. The reports from Canada show that there, too, there will be serious shrinkage, whilst from other quarters the reports are somewhat disturbing. In New South Wales and Victoria, the crops are said to be likely to be a failure owing to drought, and the reports from India, which of late years has given us so much of our wheat, are very serious. It is said that there is a serious failure of the native food crops, and that the sowing of the new wheat crop has been rendered impossible in large districts by the absence of rain. The reports from Argentine continue to point to good crops, but even there, it is said, early frosts are causing some anxiety. It is true that there is a surplus of nearly three million quarters in France, but a country which imposes an import duty of 12s. 6d. per 480 lbs. is hardly likely to become an exporter. Having regard to all the circumstances, it is difficult to avoid the conclusion that the price of wheat will rule very high during the coming winter.

False Trade Descriptions.—British manufacturers have serious cause of complaint against foreign rivals in the matter of false trade descriptions, and perhaps in no country have these descriptions been more common than in France. Complaints have been addressed to the French Government, which has inquired into the matter, and has prepared a memorandum on the subject which practically concedes the justice of the British representations. It admits, for example, that although "Savon de Windsor" may be held to be a genuine term, "Windsor Soap, London," indicates that the soap has been made in England. Such imitations cannot be reconciled with the spirit or the letter of the Madrid Convention of 1891, and the French Government have instructed the Customs administration to inform the French judicial authorities of the arrival of such fraudulent goods as soon as they are put on the market, so that they may be seized at once. And British manufacturers, whose trade has been injured, are recommended to approach the French Government with a view to the prosecution of the guilty parties by the State. The friendly action of the French Government will doubtless be appreciated by British traders, and it may be hoped that other countries, where these false trade descriptions are common, will take similar steps. It may be noted that there are numerous complaints under this head from Japan.

The Price of Wool.—Like wheat, the price of wool continues to rise, although in the case of wool the prices with which comparison is made were themselves very high. According to cablegrams from Australia, the prices ruling in the Colonial markets are above even the parity of the last London auctions. Since the opening of the season at Adelaide, some 70,000 bales have been sold in that city, Sydney, and Melbourne, and most of the wool has been bought for the Continent, more especially France. The situation is not unlike that which obtained in 1899, and which proved so disastrous to the trade. It is said in some quarters that there will be no increase in shipments from Australia this year, but it is difficult to reconcile this forecast with admitted facts as to the clip, and whether the event confirm it or not, the increase in shipments in the first three months of the present season has been very considerable. From July 1 to September 30 the shipments from Australian ports amounted to 162,000 bales. During the same period

the exports from New Zealand were 42,000 bales. Taken together, these exports exceed those for the corresponding period of last year by 46,000 bales, most of the increase coming from Australia. Since the closing of the list before the last London auctions, the arrivals of Colonial wool have amounted to 15,595 bales, of which 7,000 bales have been forwarded direct to consuming centres.

Textile Machinery.—The exports of British textile machinery in September, as shown by the Board of Trade returns, give evidence of further expansion. The total value for September this year is £652,307, as against £638,668 for September last year, and £457,254 for September, 1905. In the first nine months of the current year British textile manufacturers have shipped abroad to the value of £5,877,629, as compared with £4,810,730 for the corresponding period of last year, and £3,911,637 for the corresponding nine months in 1905. The increase in exports is most noticeable in the case of Germany—from £52,983 last year to £103,555; of "other countries in Europe" from £100,996 to £143,011; of Japan from £17,335 to £57,910; of countries in South America from £13,070 to £34,418.

Aluminium.—It is not surprising that the price of aluminium has fallen considerably of late having regard to the decline in the price of copper for which it is being largely substituted in the electrical industry, and also to the actual and nearing expiration of patents. The recent increase in the production of aluminium is remarkable, and it looks as if there will be even more rapid growth of output in the near future. The world's output of aluminium in 1899 was only 3,000 tons, in 1906 it had risen to 18,325, and some estimates for the present year double that amount. Most existing works have recently increased their output, and many new companies have been formed. The Aluminium Company of America have secured further rights over large bauxite deposits and have increased the capacity of the works at Niagara and at the Shawenegan Falls in Canada. In America the total production in 1906 was 6,500 tons as against 5,000 tons in 1905, and in Canada 2,700 as against 1,035 tons in the previous year. The British Aluminium Company are making large extensions in Scotland, and have obtained further extensive water rights at Stangfjord in Norway and Orisères in Switzerland; and two other English companies have been formed. The Aluminium Industrie Aktiengesellschaft, in addition to their works at Neuhausen and Lens, have just erected two large works at Wallis, and the two French Companies Froges expect to increase their output very largely this year, whilst the Société des Forces Matrices de l'Arve is about to devote 12,000 horse-power to the manufacture of aluminium, and the Société d'Electrochimie, 4,000. Various other projects for the production of aluminium are on foot in France, Belgium, and Italy.

Iron Ore Supplies.—It will be remembered that some years ago a company with a large capital and a directorate composed of leading ironmasters was formed to acquire large ore deposits in Norway, and by means of the Edison process, to convert the low-grade ore practically into non-phosphoric high-grade ore. The result of the experiment has been awaited with interest, since it is a matter of national importance, The rapid depletion of the iron-ore supplies is a subject of national concern, for the Spanish ore is not entirely suitable for the requirements of ironmasters, and the necessary supplies were not available elsewhere. It has long been known that in Norway there are vast deposits of iron ore but the quality of the ore is not naturally such as to make it available for commercial purposes. It is now many years since Mr. Edison first sought to devise the means whereby low grade ores could be made available for blast furnaces, and he invented a process whereby, as he claims, this object can be secured. This invention was secured by the company mentioned above with the object of applying it to the low grade ore in Norway, so as to make it available for British blast furnaces. By means of the Edison process, to quote from a description of it in the *Statist*, blocks of ore weighing anything up to five tons are dropped on to giant rollers, about five feet in diameter, faced by a series of bolted chilled iron plates, through which project rows of knobs diametrically opposed to each other, and about four inches in length, the rollers revolving at a speed of about 5,000 feet per minute. By means of a series of rollers the blocks are gradually reduced to powder, and by means of a magnet the concentrated ore, rich in iron, is separated from the remainder. Inasmuch, however, as it is impossible to use the ore in this form in blast furnaces, it is necessary to press the powder into briquettes. These briquettes, while being impervious to moisture, are at the same time sufficiently porous to allow the reducing gases in the blast furnaces to thoroughly penetrate them. It still remains to be seen whether the process can be brought to a successful commercial basis. Those directly interested in the experiment remain confident that it can be, but success has taken longer to achieve than was anticipated.

TEA.—The quantity of tea brought to auction in London from 1st July (including new season's Indian tea previously sold) as shown by the figures given in Messrs. Gow, Wilson, and Stanton's circular show a considerable shrinkage, so far as India is concerned, if compared with the corresponding figures of last season. Of Indian tea the quantity was 305,654 packages as against 340,237 last year, but the Ceylon sales increased as from 338,045 packages to 348,696 packages, whilst those from Java show the slight increase as between 26,481 packages and 27,315. The combined Indian and Ceylon teas taken in foreign and colonial markets during the first six months of this year show a slight advance upon the corresponding period last year.

Journal of the Society of Arts.

No. 2,866. VOL. LV.

FRIDAY, OCTOBER 25, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

PRIZE FOR INDUSTRIAL HYGIENE.

The Council of the Society of Arts are prepared to award, under the terms of the Benjamin Shaw Trust, a Gold Medal, or a prize of £20.

The medal, under the conditions laid down by the testator, is to be given "For any discovery, invention, or newly-devised method for obviating or materially diminishing any risk to life, limb, or health, incidental to any industrial occupation, and not previously capable of being so obviated or diminished by any known and practically available means."

Intending competitors should send in descriptions of their inventions not later than December 31st, 1907, to the Secretary of the Society of Arts, Adelphi, London, W.C.

Such descriptions may be sent in under the inventor's name, or under a motto, accompanied by a sealed envelope enclosing the name, as preferred.

The Judges will be appointed by the Council.

The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the Judges nothing deserving the full award is sent in.

UNION OF INSTITUTIONS.

The following Institution has been received into Union since the last announcement :—

Wigan and District Mining and Technical College, Wigan.

COVERS FOR JOURNAL.

For the convenience of members wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 1s. 6d. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

DETERGENTS AND BLEACHING AGENTS USED IN LAUNDRY WORK.

By Prof. Herbert Jackson, F.I.C., F.C.S.

Lecture II.—Delivered April 22nd, 1907.

The use of alkali in some form or other is probably universal in laundries. Its employment for softening water has been dealt with already. A part of this lecture will be devoted to describing the common kinds of alkali, together with simple tests for recognising them and estimating their strength, and to a short consideration of their value as detergent agents.

The Table (p. 1102) gives the names and formulæ of the alkalies which are most likely to be met with.

The first column of numbers gives the parts of each alkali equivalent to any other one in power of neutralising an acid such as sulphuric acid, and the second set of numbers represents the percentage of what is frequently described as real alkali, *i.e.*, oxide of sodium (Na_2O). The equivalents do not represent the parts of alkalies of equal value in all other respects, as for instance for washing purposes, except in the case of strictly comparable forms of alkalies, such for example as the five different varieties of sodium carbonate, in four of which water enters into the composition. Here the equivalents truly represent the values, and whatever may be done by using 143 parts of the highest hydrate of sodium carbonate, viz., $Na_2CO_3 \cdot 10H_2O$, may be equally well effected by 53 parts of pure anhydrous Na_2CO_3 dissolved in the same volume of water. Strictly speaking, to make two such solutions perfectly comparable the water combined in the hydrated carbonate ought to be taken into account, but with the weak solutions employed in laundry practice this need not be considered at all.

The various alkalies can be distinguished from one another by simple tests such as the following, which are to be applied to cold solutions of the substances. Caustic soda gives a brown precipitate with a solution of silver nitrate which may be quite dilute. Caustic potash gives the same reaction, but a solution of this substance made acid with tartaric acid and stirred with a glass rod will give a white precipitate of potassium bitartrate while caustic soda will give no such precipitate. Silver nitrate will give precipitates with other alkalies, but no brown precipitate except possibly in the case of a warm rather dilute solution of borax which is easily distinguished by the test, to be given for this substance. Sodium carbonate and bicarbonate give brisk effervescence when treated with acid such as dilute sulphuric acid. They may be distinguished in solution by adding a solution of magnesium sulphate, which gives a white precipitate with sodium carbonate in the cold but none with sodium bicarbonate until the solution is heated. Borax can be identified as follows. Add to its solution dilute hydrochloric acid till blue litmus is just reddened, indicating that the acid is in slight excess. Dip a small strip of paper dyed with the yellow dye turmeric into this slightly acidified solution, and dry the paper by a gentle heat. A red colour will be formed, which is changed to dark green by a solution of caustic potash or soda. Turmeric paper goes brown with alkalies alone.

Solutions of silicate of soda, unless very dilute indeed, will quickly give a white gelatinous precipitate of hydrated silica if they are treated with a solution of ammonium chloride (sal ammoniac). No test for ammonia beyond the smell need be mentioned. It will be understood that the tests given are to be applied to simple solutions of the alkalies mentioned. It would lead to analytical details out of place here to enter into the methods of identification of the different alkalies in all the mixtures which may be offered to the launderer. But as it is advisable for him never to deal with alkalies except in their simple forms as recognised chemical substances, purchased under their proper names, and to make such mixtures as he may desire himself, the occasion for more elaborate testing will hardly arise. What is important is that he should be able to gauge the strengths of solutions of alkalies and to determine the values of the different varieties which he uses. For this purpose it is necessary to describe in some detail the methods of making standard solutions of acids and alkalies and of using them in analysis, together with the behaviour of certain substances employed to indicate whether a solution is acid, alkaline or neutral. The principle of such analysis is easily understood by a simple illustration. Suppose the launderer to have in his possession a sample of sodium carbonate known to be nearly pure and some dilute sulphuric acid. Then, without knowing anything of the strength of the acid, he can obtain a very fair idea of the value of some other sample of sodium carbonate as compared with the good one in the following manner. Let him dissolve a convenient weight of the good sample, say a quarter of an ounce, in distilled water, and from a graduated vessel add the dilute sulphuric acid little by little until the solution is shown to be just acid by its distinctly reddening blue

Name.	Formula.	Equivalent.	Na_2O per cent.
Caustic soda	$NaOH$	40	77·50
Sodium carbonate	Na_2CO_3	53	58·49
Crystal carbonate	Na_2CO_3 H_2O	62	50·00
Sodium sesquicarbonate	Na_2CO_3 $NaHCO_3$ $2N_2O$	75·3	41·15
Different hydrates of sodium carbonate	Na_2CO_3 $5H_2O$	98	31·63
	Na_2CO_3 $7H_2O$	116	26·72
Washing soda (soda crystals)	Na_2CO_3 $10H_2O$	143	21·67
Sodium bicarbonate	$NaHCO_3$	84	36·9
Sodium silicate (soluble glass)	(a solution of $Na_2Si_2O_5$ which varies in strength)		
Sodium silicate (Alkasil)	Na_2SiO_3 $9H_2O$	142	21·83
Borax	$Na_2B_4O_7$ $10H_2O$	191	16·23
Ammonia	(a solution of about 34°/0 real NH_3. The equivalent of NH_3 is 17)		
			K_2O per cent.
Caustic potash	KOH	56	83·92

litmus paper, noting the number of measures of sulphuric acid required to bring this about. If then he weighs a quarter of an ounce of the other sample and, proceeding in an exactly similar manner, finds that only three-quarters of the amount of the dilute sulphuric acid used in the first experiment are now required, it is clear that the sample has only 75 per cent. of the value of the good specimen of sodium carbonate. Although the strength of the acid was not known, the data had in reality been obtained for calculating it. If the test sample of sodium carbonate had been as pure as possible, the weighing and measuring accurate, and an indicator more suitable than litmus for use with cold solutions had been employed, a simple calculation would have given the actual value of the sulphuric acid. Expressed as an equation, the action of sulphuric acid on sodium carbonate is—

$$Na_2CO_3 + H_2SO_4 = Na_2SO_4 + H_2O + CO_2,$$

which represents the known fact that 106 parts of sodium carbonate and 98 parts of sulphuric acid (H_2SO_4) react on one another to produce neutral sodium sulphate, water and carbonic acid gas being formed at the same time. In the table of equivalents the number for Na_2CO_3 is given as half 106, or 53, so as to compare the molecule of Na_2CO_3, which contains two atoms of sodium (Na) with caustic soda and sodium bicarbonate, the molecules of which have only one atom of sodium in them. Halving the number 98, which is the molecular weight of sulphuric acid, gives the equivalent 49, representing the parts of this acid which will neutralise the number of parts of any of the alkalies given in the column of equivalents in the table. It follows, therefore, from what has been said that it is only necessary to be certain of the purity of a specimen of some one of the different alkalies, to be in a position to weigh and measure with reasonable accuracy, to know the proper indicators to use and the most convenient strengths of solutions of acids and alkalies to work with, in order to be able to obtain the values of any of the other alkalies or solutions of them with ease and considerable accuracy after a litttle practice. The best alkali to take as a standard is sodium carbonate. It can be obtained in a condition of great purity, and the only other substances likely to be present are a little water and perhaps a small amount of sodium bicarbonate. Before preparing a standard solution from it, about 30 grams should be heated to a dull red heat in a porcelain dish for about half an hour. This will expel the water and convert bicarbonate into carbonate. When cold, 26·5 grams are to be weighed out and transferred to a flask capable of holding 500 cubic centimetres of water, this volume being indicated by a mark on the neck of the flask. Distilled water is added in such a quantity as to make it convenient to shake up the contents, and, when all the carbonate has dissolved, water is added up to the mark. Such a solution contains sodium carbonate in the proportion of its equivalent, viz., 53 grams, in one litre. It is generally spoken of as a normal solution, and solutions of any alkalies or acids containing their equivalents in grams per litre would also be described as normal solutions of those alkalies or acids. They are convenient solutions to use, since a measure of any one of them is the chemical equivalent of an equal measure of any other. The standard solution of acid is made from strong sulphuric acid (oil of vitriol). This always contains a little water, so that it is not possible to obtain the right amount of it by direct weighing. The simplest plan to adopt is to measure off 30 cubic centimetres of the strong acid in a graduated vessel and to pour this carefully into about 200 cubic centimetres of distilled water in a beaker, washing out the vessel with a little more water. When the mixture is cold, it is transferred to a litre flask and distilled water is added up to the mark on the neck of the flask. The actual weight of acid (H_2SO_4) which is required in the litre is 49 grams, *i.e.*, the equivalent of sulphuric acid. Taking the specific gravity of the strong acid as 1·84, the 30 cubic centimetres would weigh appreciably more than 49 grams, but the solution is made stronger so that it can be diluted to normal strength after its value has been found, in the following manner. A convenient volume, say 20 cubic centimetres of the normal solution of sodium carbonate, is accurately measured into a small flask, and some of the solution of acid is added from a graduated vessel, such as a burette marked in cubic centimetres and tenths of cubic centimetres, until the alkali is exactly neutralised. Before adding the acid, a drop or two of a solution of methyl orange is put into the flask with the solution of sodium carbonate to act as an indicator. The colour will be yellow so long as the reaction is alkaline, and the acid is to be added until this colour just changes to a reddish pink, which indicates a very slight excess of acid. Very little indicator should be used, as the change is more noticeable with faint colours. (A

useful solution of methyl orange is made by dissolving a quarter of a gram of the solid substance in 250 cubic centimetres of dilute alcohol, about 30 per cent. strength. The solution will keep indefinitely.)

If the sulphuric acid solution had been normal, the reading of the burette would show that 20 cubic centimetres were required to neutralise the same volume of alkaline solution in the flask, but as the acid was purposely made too strong, less than this amount would certainly have been used from the burette, and a calculation from the result can be made to find the extent to which the solution must be diluted to bring it to normal strength. For example, suppose the reading of the burette had shown that 18 cubic centimetres had been added to the 20 cubic centimetres of normal sodium carbonate, and were therefore equal to them in strength. Then $\frac{18 \times 1000}{20} = 900$ cubic centimetres of the acid are equal to 1,000 cubic centimetres, *i.e.*, one litre of the standard. The dilution, therefore, of 900 cubic centimetres of the acid to one litre with distilled water, will bring it to normal, that is to a strength of 49 grams of H_2SO_4 per litre. For most purposes a solution of one-tenth, this strength spoken of as a decinormal or $\frac{N}{10}$ solution, is more generally employed and is made readily from the normal acid by diluting 100 cubic centimetres of the latter with distilled water to one litre. Each cubic centimetre of this weaker acid contains ·0049 grams of H_2SO_4, and is capable of neutralising the one ten-thousandth part of each of the equivalents given in the table of alkalies, using methyl orange as the indicator. Whether the stronger or weaker acid is used will depend on the accuracy with which samples of alkali can be weighed out. If the balance available is a rough one, only capable of turning with a centigram, the normal acid should be used. For example, suppose it is desired to value a certain sample of sodium carbonate. If the normal acid is to be employed, weigh out 10 grams of the sample and dissolve them in distilled water, making the solution up to 250 cubic centimetres. Measure 25 cubic centimetres into a flask and add normal acid from a burette until neutrality is indicated. Let it be supposed that 12 cubic centimetres are required. Then as each cubic centimetre of normal acid is capable of neutralising ·053 grams (*i.e.*, the one-thousandth part of the equivalent) of sodium carbonate $12 \times \cdot053 = \cdot636$ is the amount of Na_2CO_3 present in the 25 cubic centimetres tested or 6·36 grams of real Na_2CO_3 in the 10 grams which were dissolved, *i.e.*, 63·6 per cent., the rest being probably water. With decinormal acid 1 gram of the sample can be dissolved and the solution made up to 250 cubic centimetres, the subsequent procedure being the same, and the calculation made for the equivalent of the weaker acid. One of the advantages of using the weaker acid is that a litre of normal acid once made carefully and kept in a stoppered bottle will last a long time as the source of several litres of the decinormal acid, and if the balance used is sufficiently delicate results of considerable accuracy can be obtained, while several determinations can be made, not only of samples of alkali, but of the alkalies in soaps, and in any of the solutions used in the laundry, without the fear of using up a standard acid which had taken some time to prepare. It is impossible in the time which can be devoted to this part of the subject to give details of all the applications of standard acids and alkalies which can be made in a laundry, but before passing on to the action of alkalies as detergent agents, some reference must be made to another useful indicator, viz., a solution of phenol phthalein and to the well known litmus. When sulphuric acid acts on sodium carbonate, borate, or silicate, the acids—carbonic, boracic and silicic are liberated. None of these has practically any effect on methyl orange, and therefore all the alkali considered as Na_2O present in the compounds mentioned, is used up in neutralising the sulphuric acid with which they may be treated. In the case of litmus, such a weak acid as carbonic acid has a partial effect, and consequently this indicator can only be used to give good results with alkaline carbonates if the carbonic acid as it is liberated is expelled by boiling. Litmus is not suitable as an indicator with borates and silicates, but it may be used with caustic alkalies. Phenol phthalein is affected by carbonic acid to such an extent that it shows no reaction with solutions of sodium bicarbonate, and this property makes it a very useful indicator when it is required to determine the constitution of mixtures of caustic soda and sodium carbonate, or of the latter with sodium bicarbonate. This use of phenol phthalein is best shown by taking two examples. Suppose that it is desired to find the amount of carbonate in a sample of caustic soda. Weigh out one gram of the sample and make up a solution of it, in

distilled water, to 250 cubic centimetres. Find the volume of decinormal acid required to neutralise 25 cubic centimetres of this solution, using methyl orange as the indicator. As an instance let this volume of acid be 22 cubic centimetres. Then do the same experiment but with phenol phthalein as the indicator. A smaller volume of sulphuric acid will be found to be required if any carbonate is present. As an example let this volume be 20 cubic centimetres. The method of calculating is as follows. With phenol phthalein all the caustic soda is shown, but only half the sodium carbonate, since when half of it has been neutralised the sodium carbonate has become sodium bicarbonate, to which phenol phthalein does not respond. Therefore double the difference between the volumes of acid used with methyl orange and phenol phthalein represents the amount of acid required for the sodium carbonate present. Hence in the instance taken the volume of $\frac{N}{10}$ acid required for the Na_2CO_3 present in 25 cubic centimetres of the solution is double the difference between 22 and 20, that is to say 4 cubic centimetres. As 1 cubic centimetre of $\frac{N}{10}$ acid is equivalent to ·0053 grams Na_2CO_3, the amount of this substance present in ·1 gram of the sample is $\cdot 0053 \times 4 = \cdot 0212$ grams or 21·2 per cent. The percentage of caustic soda (NaOH) is found from the amount of acid used, which has yet to be accounted for in the determination with methyl orange as indicator. This is 22-4 or 18 cubic centimetres, which were therefore used up to neutralise the NaOH in the 25 cubic centimetres of solution taken. From the table of equivalents it is seen that 1 cubic centimetre of $\frac{N}{10}$ acid neutralises ·004 grams caustic soda. Hence the amount of NaOH present in ·1 gram of the sample is $18 \times \cdot 004 = \cdot 072$ grams or 72 per cent., leaving 6·8 per cent. of the sample to be accounted for as water, or possibly neutral salts. The two determinations, one using methyl orange and one with phenol phthalein, are made in the same way for mixtures of sodium carbonate and bicarbonate, and again the method of calculation may be shown by an example. One gram of a sample of sodium carbonate which had been exposed to the air and was suspected to contain bicarbonate was dissolved in water and the solution made up to 250 cubic centimetres. Using methyl orange as the indicator, 25 cubic centimetres of the alkaline solution required 15 cubic centimetres of $\frac{N}{10}$ sulphuric acid for complete neutralisation. With phenol phthalein the volume of acid needed was 6·5 cubic centimetres. As only half the sodium carbonate and none of the bicarbonate is shown with phenol phthalein, the volume of acid used with this indicator was doubled, giving, therefore, $\cdot 0053 \times 13 = \cdot 0689$ grams of Na_2CO_3 as the amount present in ·1 gram of the sample, that is say 68·9 per cent. The rest of the acid, viz., $15 - 13 = 2$ cubic centimetres went to neutralise the sodium bicarbonate. From the table of equivalents 1 cubic centimetre of $\frac{N}{10}$ sulphuric acid neutralises ·0084 grams of sodium bicarbonate ($NaHCO_3$). Therefore, the amount of this present in ·1 gram of the sample was $\cdot 0084 \times 2 = \cdot 0168$ grams, $NaHCO_3$, or 16·8 per cent., leaving 14·3 per cent. of water in the sample. (A solution of phenol phthalein may be made by dissolving 1 gram of the solid in a little strong alcohol, and making up the solution to 250 cubic centimetres with alcohol of about 40 per cent. strength. The solution does not alter on being kept, and a few drops only are needed each time it is used as an indicator. The alcohol used should of course be free from any appreciable amount of acid.) The subject of determining the values of alkalies has been dealt with somewhat fully because experience shows that there is no greater and more fruitful source of trouble than the indiscriminate use of alkaline solutions for washing purposes. It is of very great importance that the launderer should be able to ascertain for himself the strength of the alkalies which he uses and not have to depend on statements made in advertisements or otherwise.

In some instances it is probable that one of the chief reasons for employing alkali in one form or another is to effect a saving in the consumption of the more expensive detergent soap. The action of alkali to soften water has been dealt with in the first lecture. Where a water is not softened in bulk before being used for washing, it is clear that some alkali must be used to prevent an unnecessary and foolish waste of soap, but the use of a large amount over and above what is required for this purpose is undoubtedly to be condemned. It is frequently stated that one of the effects of alkali is to saponify the fats and grease which are always present to some extent in the various articles sent to a laundry to be washed. Direct experiment shows that the extent of saponification brought about by such an alkali as sodium carbonate even in the greatest strength in which it is probably ever used in laundry work, is very slight indeed. Where

free fatty acids occur in clothing, &c., the alkali does neutralise them practically completely, but so far as fats are concerned its action appears to be dependent on the property which most alkalies have when their solutions are shaken with fats or oils, of producing emulsions consisting of separated globules of fat in a fine state of division. It seems very probable that in this particular instance of emulsification some chemical action does take place to a small extent in the direction of saponification, and that this slight action is necessary for the production of a successful emulsion. Oils or greases which are free from all saponifiable matter will not yield any emulsions when shaken up with plain aqueous solutions of alkalies, but the addition of a little saponifiable oil or fat makes it possible to hold a fair amount of the unsaponifiable grease in a mechanical state of emulsion lasting long enough to allow of its being washed away. With regard to the relative values of different alkalies as emulsifying agents, experiments with caustic soda, ammonia, sodium carbonate, borax and sodium bicarbonate show that so far as the first four are concerned, and dealing with commonly occurring fats and oils, there is practically nothing to choose between them if an equivalent quantity of each is taken.

It might well be expected that caustic soda on account of its greater activity as a saponifying agent would be superior to the other alkalies, but emulsions made with it, and with equivalent quantities of sodium carbonate, borax and ammonia, and the same amount of fats and oils, show no practical difference even after being kept for some months. An emulsion made with borax is the most lasting of all. Sodium bicarbonate can scarcely be called an emulsifying agent. Its power in this respect is less than one-fiftieth of that possessed by an equivalent quantity of any of the other four alkalies mentioned. It is not possible to give any exact data of the amounts of fat or oil held in a state of emulsion by alkalies, as the conditions of experiments vary, and some kinds of fat emulsify more easily and completely than others, but as some guide it may be mentioned that a variety of experiments show that one part of caustic soda, or the chemical equivalent of the other alkalies described as good emulsifying agents, will hold about forty parts of the average kinds of grease and oil met with in a state of emulsion lasting a considerable time, even when the actual strength of the alkaline solution is not greater than about ·05 per cent. The emulsifying power of soap is also considerable, but it is increased materially by the addition of more alkali. Another reason for using some alkali in connection with soaps, is to be found in the tendency, which is noticed in the case of some soaps, to the formation of insoluble or sparingly soluble acid soaps, as a result of the action of water. These may give rise to trouble in the form of spots and marks, which frequently do not show up until the washed article is finished and ironed. The addition of a little alkali, such as sodium carbonate, along with the soap, when the latter is being dissolved, will often prevent the formation of such acid soaps although, when once formed, a great deal of alkali may fail to dissolve them. Hence the alkali should be added with the soap, and not after this has dissolved and so had time to be affected by water.

It will be gathered from what has been said, that for much of the ordinary work which has to be done in a laundry the use of some alkali is practically a necessity. The questions of importance which arise, therefore, are which alkali to use, and in what strength to use it, so as to avoid the danger of damaging the articles to be washed.

In answer to the first question, it may be said at once that the use of caustic soda is to be condemned. No launderer of experience would, of course, think of treating woollen goods with any form of free alkali, but as examples have been found in actual practice of damage done to woollen materials which could only be ascribed to the action of alkalies, it may be as well to point out the various changes brought about by the action of even so dilute a solution of caustic soda as one containing ·05 per cent. of NaOH. The solvent action of alkalies on wool will be referred to again in the next lecture, but for the present it will be of interest to consider the extent of the action of caustic soda in comparison with that of sodium carbonate, borax, and ammonia.

A large number of experiments have been made in this direction, the details of which would occupy too much time to give even in outline, but the general conclusion arrived at may be stated briefly and illustrated with photo-micrographs of specimens of wool fibre before and after treatment with alkalies. As anything like a 1 per cent. solution of caustic soda at a temperature of 32° Cent. (90° Fah.) allowed to act on wool for some time will completely disintegrate and destroy it for all practical purposes, reference will only be made

to the action of a solution of ·05 per cent. strength at the same temperature. This is found to be practically at least twenty times as great in rendering woollen fabric harsh, brittle, and shrunken up as the action of an equivalent

FIG. 1.

solution of sodium carbonate. To illustrate this Figures 1, 2, 3, and 4 are given. Fig. 1 shows a fibre from flannel before treatment. Fig. 2 a fibre of a portion of the same flannel after treatment at 90° Fah., with ·05 per cent. solution of caustic soda. Fig. 3 a fibre from

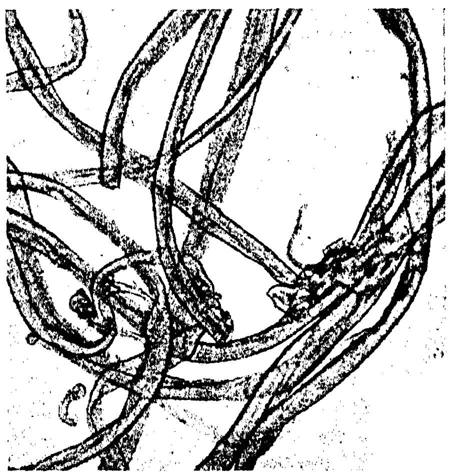
FIG. 2.

another portion after treatment with a solution of sodium carbonate containing 1·3 per cent. of Na_2CO_3, *i.e.*, twenty times the equivalent of ·05 per cent. NaOH. The magnification for these three was 300 diameters. Fig. 4 is a photograph of a few fibres from a small, hard, and felted piece from the same portion of flannel as that used for Fig. 3. The magnification in this case was 120 diameters to show the general twisting and breaking up resulting from the action of the alkali.

FIG. 3.

It is not suggested that all the fibres in the pieces of treated flannel were as broken and damaged as those shown. They have been chosen from a number of similar ones to show what is to be considered as the effect which would follow the prolonged or repeated action

FIG. 4.



of alkalies of the strengths mentioned, and it is not intended to convey the idea that every piece of woollen material rendered harsh and unpleasant to the touch, and with the natural spring destroyed by the use of alkali would

necessarily show such extensive destruction of the fibre. Sooner or later, however, a very similar result would follow as the weakened material was subjected to ordinary wear and tear.

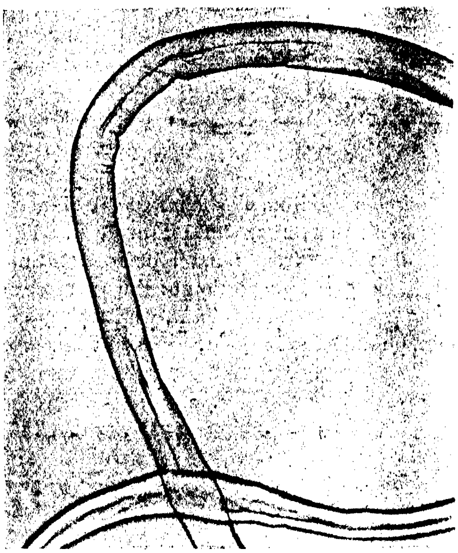
Solutions of borax (4·6 per cent. $Na_2B_4O_7 . 10H_2O$) and ammonia (·42 per cent. real NH_3) equivalent in strength to the 1·3 per cent. solution of sodium carbonate, and allowed to act on wool in the same manner gave results showing decidedly less indication of destruction to the fibre, but the wool was rendered harsh and impoverished. Caustic potash has at least as much effect on wool as caustic soda. It has been said that no free alkali of any kind should be used in washing woollen articles since sufficient neutral soap, given the time to act, will cleanse even very greasy material of this nature, but should the occasion arise when a little alkali appears to be a necessity, experiments show that weak solutions of borax of about ·5 per cent. strength will materially assist in the removal of grease and greasy stains with the least damaging effect on the wool fibre. A solution of ammonia containing ·05 per cent. of real NH_3 is about equivalent to the borax solution and has much the same effect.

Silk is affected by alkalies in much the same way as wool, and although the effect on the fibres is not so apparent under the microscope, they are much weakened and left in a condition which in time developes into one of general disintegration. Borax again has the least effect, but ammonia unless quite weak soon deteriorates silk.

The action of alkalies on cotton and linen is well known to be very much less harmful than that on wool and silk. In the process of mercerisation, cotton is treated with a strong cold solution of caustic soda, the effect being to form a compound of the cellulose with the alkali, and to shrink and thicken the fibre, which is changed from a flat riband into a cylindrical form. The swollen appearance may be seen in Fig. 5, which is a photo-micrograph of a treated fibre.

The alkali compound of the cellulose is unstable, and is changed by water to a cellulose hydrate, the alkali being dissolved in the water. This change does not seem to be accompanied by any visible disorganisation of the fibre, which is found to have gained in tensile strength. It might appear, therefore, at first sight, as if no danger need be apprehended from the use of alkali in washing cotton goods, but it must be remembered that there is a great difference between a single treatment with alkali in the cold followed by a thorough washing, and the constant use of hot solutions of an alkali such as sodium carbonate. Even supposing the solution used to be a dilute one, there is the danger, through insufficient rinsing, of concentration of the alkali on drying, and of its action at a high temperature in any subsequent process of ironing. Direct experiment, and the examination for alkali of several examples of washed and finished articles, such as table linen and cotton sheets, &c., have proved that this danger is a very real one, and that the use of much alkali will inevitably weaken and disin-

FIG. 5.

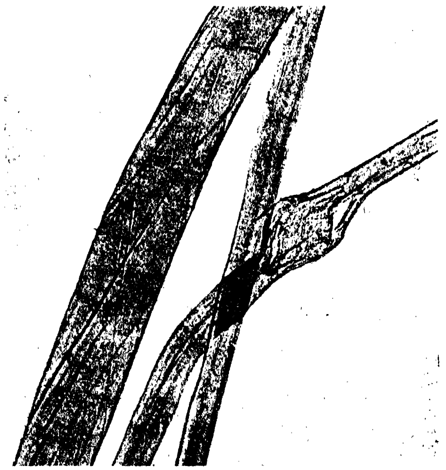


tegrate cotton and linen in a much shorter time than that in which anything like the same change could be brought about by the action of soap and water alone. The effect of alkali on linen fibre can be made more apparent than that on the fibre of cotton.

The accompanying Fig. 6 represents fibres of linen, in the broadest of which distinct oblique markings are visible. These were not to be seen before the fibre was affected by alkali. The treatment was carried out under the microscope, the fibre being soaked in hot alkaline solution, washed and dried, and the process repeated six times. The markings were observed to increase in extent and distinctness as the treatment progressed, and may, therefore, be considered to be indications of approaching disintegration of this fibre.

Another and cogent reason for avoiding the use of strong alkaline solutions in washing cotton or linen articles is that the production of a bad colour is almost certain to follow. Experiments made with different pieces of the same samples of linen and cotton washed about ten times in plain neutral soap solution, and in solutions of soap with varying strengths of alkali, showed that a distinct difference in colour could be seen even when so dilute a solution of sodium carbonate as one containing ·1 per cent. of Na_2CO_3 was used. To advise that no alkali should be employed in washing linen and cotton would be to offer a counsel of perfection which it would be unreasonable to hope could possibly be followed in view of the amount of grease and dirt which is so often present in articles sent to a laundry. What may reasonably be said is that the quantity of alkali used is often out of all proportion to that required, and that the very strength of the solutions defeats the object of the launderer, not only by discolouring the goods, but frequently also by preventing the removal of very finely divided dirt. The character of the work in laundries varies so much that it is impossible to make any very definite statement as to the strength of alkali to be used. For the general average of linen and cotton articles a ·1 per cent. solution of sodium carbonate Na_2CO_3 (one pound to 100 gallons of water) may be considered to represent the superior limit of strength, and a ·05 per cent. solution will certainly give better results with less danger to the material, but will require the expenditure of more soap and a longer time.

FIG. 6.



It may not be out of place here to repeat the advice that every one who has to direct the processes in a laundry should familiarise himself with the methods and practice of determining the strength of alkaline solutions. It has happened on some occasions that a change has been made from an hydrated form of sodium carbonate to anhydrous sodium carbonate without any alteration in the weight used for the same volume of water. Reference to the table of alkalies and their equivalents, will show that this may very well have meant unintentionally doubling the amount of real alkali dissolved with, no doubt, some saving in soap and probably time, but with the accompanying trouble of bad colour and deteriorated material. The use of caustic soda, instead of sodium carbonate, for washing linen and cotton, is to be condemned. It is true that, in very careful hands, the use of small amounts of caustic soda has not appeared to be open to any reasonable objection, but it is doubtful in such cases whether caustic soda was really the agent employed in the actual washing. In three instances in which the washing fluid was examined, it was shown that the amount of available carbonic acid present in the water was sufficient to convert practically the whole of the caustic soda added into sodium carbonate which was, therefore, the form of alkali to the action of which the articles were in reality subjected. The addition of more caustic soda, so as to use some in the free state, was soon followed by the appearance of a brown colour on some of the linen articles washed. As a rule, linen shows the brown stains due to alkali in a much shorter time than cotton.

The subject of bleaching agents is of considerable importance and interest to those engaged in laundry practice. It is, of course, to be understood that bleaching by special agents should never form part of the ordinary process of washing. The practice of always putting a certain proportion of bleach into the washing fluids used to clean white linen and cotton goods, with a view to improving their colour, is bad, and against the interests alike of the launderer and the owners of the articles. It is easy to give the advice that no quick bleaching agents should ever be employed under any conditions, but so long as the launderer is asked and expected to remove obstinate stains in one washing, and to leave no visible trace of them, he must have recourse to some agent other than the usual detergents. Many stains can undoubtedly be removed, if

sufficient time and individual attention be given to them, by the use of soap and water, and a little mild alkali, such as borax, but it is practically out of the question to expect this to be done in a laundry in which a large amount of work has to be completed in a specified time. If bleaching in some cases is, therefore, practically demanded of the launderer, it is important that the nature of the bleaching agents used, and the best strengths of their solutions should be fully understood, so as to avoid as far as possible any serious damage to the articles bleached.

The bleaching agents, the relative values of which have been tried, are given in the following list:—

Light.

Chlorinated lime.

Chlorinated soda.

Hydrogen peroxide.

Hydrogen peroxide with very dilute ammonia.

Potassium permanganate, followed by sulphurous acid.

Potassium permanganate, followed by oxalic acid and a little very dilute sulphuric acid or acetic acid.

Potassium permanganate, followed by hydrogen peroxide and very dilute sulphuric acid, or acetic acid.

Sodium peroxide alone, or with magnesium sulphate.

Electrolytic bleach.

Soaping and exposing on grass throughout dewy nights.

Ozone.

Sulphurous acid.

Potassium metabisulphite.

Sodium hydrosulphite.

Titanous chloride.

Stannous chloride.

To these may be added oxalic acid, if its action in removing iron stains can be spoken of as bleaching.

The eleven substances following Light on this list, owe their bleaching properties to the readiness with which they add oxygen to many colouring matters, the fully oxidised compounds of which are practically colourless. Sulphurous acid, and those following it, act as reducing agents, that is, they remove oxygen from certain colouring matters, the de-oxidised products which result, being either colourless, or much less highly coloured than the original substances. As a rule, bleaching by reducing agents is less permanent than that accompanying further oxidation, the colour returning to some extent on exposure to light, or often when the bleached material is treated with soap or alkalies. The action of light is to favour the absorption of oxygen from the air, and to restore the reduced compound to its original condition. A still longer exposure to sunlight, by promoting further absorption of oxygen, will frequently bring about a second bleaching in a manner analogous to that in which an oxidising substance, such as hydrogen peroxide, acts. Bleaching by light is the most desirable of all processes and causes the least possible deterioration of fabrics. It is unfortunately impracticable in most towns, besides being a very slow process in the case of refractory stains. The agent which is most usually employed is chlorinated lime or soda. The active agent is chlorine in a state capable of effecting oxidation in the presence of water. A fair specimen of chlorinated lime should contain from 30 to 35 per cent. of such available chlorine. Either in the form of the lime or soda compound this bleaching agent is wholly inapplicable in laundry work to woollen or silk articles, the fibres of which are attacked by chlorine and rendered harsh and brittle. Its use is restricted to the bleaching of linen or cotton, the cellulose of which is, however, by no means unaffected by chlorine although possessing much less affinity for this oxidising agent than wool. It is necessary, therefore, to exercise great care in the employment of a chlorine bleach, and the following directions are given as a suggestion for making and using either chlorinated lime or soda solutions in the strongest form which experience shows it is reasonably safe to adopt.

Six lbs. of chlorinated lime are to be well mixed with 100 gallons of water and the mixture allowed to settle. The clear liquid only is to be used, and it will be found to contain from ·14 to ·2 per cent. of available chlorine, according to the richness in chlorine of the lime compound dissolved.

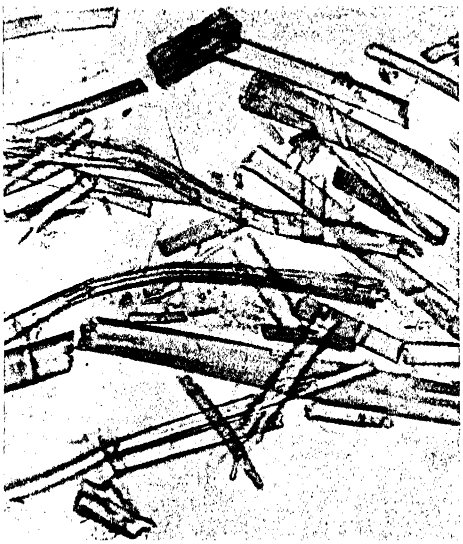
For a solution of chlorinated soda, 5 lbs. of chlorinated lime are to be thoroughly mixed with 6 gallons of water, and to this mixture are to be added 4 gallons of water in which $6\frac{3}{4}$ lbs. of anhydrous sodium carbonate (Na_2CO_3) have been dissolved. The whole is to be well stirred up and then allowed to settle. For use one pint of the clear fluid is to be diluted with water to one gallon. This diluted solution will contain practically the same percentage of available chlorine as the solution made from chlorinated lime.

Whichever solution is used, the fabric after having been steeped in it should be trans-

ferred without rinsing to a bath of either a solution of acetic acid containing about 2·5 per cent. of glacial acetic acid, or a solution of sulphuric acid containing not more than ·8 per cent. of pure acid (H_2SO_4), *i.e.*, 1° Twaddell (1·005 specific gravity).

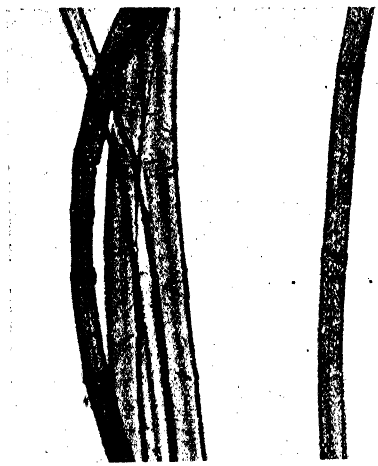
In all instances the solution of acetic acid is to be preferred. The main bleaching agent in this case is hypochlorous acid which is liberated by the acetic acid from calcium or sodium hypochlorite present in the solution of chlorinated lime or soda, calcium or sodium acetate being formed at the same time. The hpyochlorous acid (HOCl) bleaches by parting with its oxygen and becoming

FIG. 7.



thereby converted into hydrochloric acid, HCl. This acid in turn reacts on either calcium or sodium acetate to form the chlorides of these metals, liberating acetic acid, which, therefore, is finally left as the only free acid present with the fabric. Thorough rinsing should follow the bath of acid, but the advantage of using acetic acid lies in the fact that should traces of this acid be left in the fabric it will have little, if any, bad effect on the fibres in the subsequent processes of drying and ironing. When a bath of sulphuric acid is used instead, the principal bleaching agent is free chlorine, which becomes converted in the course of its reaction on the colouring matter into hydrochloric acid. Part of the sulphuric acid forms calcium or sodium sulphate, but some will be left in the free state along with the hydrochloric acid. Very complete rinsing is therefore necessary, and it is advisable to make sure of the absence of any possible free acid either by adding a little alkali to the last rinsing but one, or else by washing the articles once again with soap in the usual manner. It has been found that much of the damage done by bleaching is often attributable to the free acid left in the fabric. However dilute the solution may be, the acid becomes concentrated on drying and heating, with the result that the fibres of linen or cotton which are rapidly affected by free acid become disorganised and break up into small pieces. Linen fibre, from its difference in structure, is

FIG. 8.



more easily affected by chlorinated lime or soda solutions and other oxidising agents than cotton.

The general effect of badly conducted bleaching is illustrated in Fig. 7, which is a photo-micrograph of disintegrated fibres of linen seen under a magnification of 250 diameters.

Fig. 8 shows some fibres of the same piece of linen before treatment. The transverse markings which give the fibres somewhat the appearances of bamboo canes vary in different specimens of linen fibre. They are not visible in the actual bast fibres of the plant, but become apparent after the process of manufacture into flax. It is principally at these markings or nodes that the breaks occur when linen is subjected to injudicious chemical treatment, but the fibres are also seen to split longitudinally.

Fig. 9 illustrates the appearance under the microscope of mechanical injury done to linen

fibre by the rough treatment which it often receives during the preparation of the fabric.

Fig. 10 is a photo-micrograph of a small piece of cotton fibre damaged by bleaching and showing one end just ready to break off.

With reference to Fig. 9, it may be mentioned that mechanical injuries of the kind shown do not appear in old linen which is known to have been in use for many years to anything like the same extent as is to be seen in many examples of modern linen. Such injuries naturally weaken the fibres considerably, and experiments have shown that specimens of well-preserved old linen will still stand without injury a treatment which reveals the undoubted weakness and structural disorganisation of the fibres of many

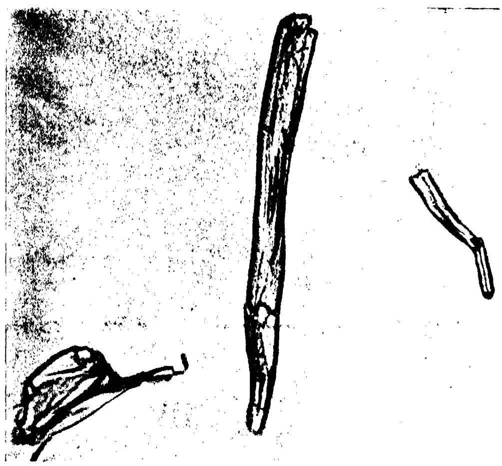
FIG. 9.

samples of new linen of recent manufacture. Bleaching by potassium permanganate followed by sulphurous acid was first introduced by Professor W. N. Hartley in 1869 as a process specially applicable in the preparation of white linen. When used with care the effect on the fibres of linen and cotton is very slight and the process may also be adapted to the bleaching of stains of an organic and easily oxidisable nature on wool and silk if precautions are taken to avoid strong solutions of the ingredients. The following directions are given for making and using the strongest solutions which should ever be used. Steep the fabric in a solution containing one ounce of potassium permanganate ($K_2Mn_2O_8$) dissolved in one gallon of water until a definite brown colour has been produced. Then wash thoroughly in water.

Place the browned fabric next in a solution containing one lb. of sodium sulphite ($N_2SO_3 \cdot 7H_2O$) dissolved in one gallon of water to which three fluid ounces of sulphuric acid (oil of vitriol of specific gravity about 1·8) have been added. (This gives a solution containing about 3 per cent of sulphurous acid, H_2SO_3). Leave the fabric in it until all brown colour has disappeared. Rinse thoroughly in water and give a final wash with the soap in the ordinary way.

Linen and cotton do not assume a brown colour so readily as wool and silk, and require, therefore, longer steeping in the permanganate solution. The strengths of the solutions may with advantage be about half those given when wool or silk are to be treated. The action of the permanganate is, however, selective, and an organic stain on linen or cotton will become dark brown long before the rest

FIG. 10.



of the fabric is much coloured. When the stain has assumed a dark colour there is no object in continuing the steeping in the permanganate solution. At no stage of the bleaching process should the fabric be allowed to dry. The brown colour is due to the deposition of hydrated manganese dioxide formed from the permanganate when the latter gives up part of its oxygen to the organic matter of the fabric or the stains. The action of the sulphurous acid consists in the removal of part of the oxygen from manganese dioxide with the formation of sulphuric acid, which remains in combination with the lower oxide of manganese as soluble manganese sulphate. The thorough washing advised is necessary because if sulphurous acid were left in the fabric some of it would be oxidised by the air to sulphuric acid, and besides there is sure to be a certain small amount of sulphuric acid free in the solution. It will be

seen that the fabric is alternately exposed to the oxidising influence of potassium permanganate, and to the de-oxidising or reducing action of sulphurous acid. In the case of linen or cotton goods this acid is quite a suitable agent to employ to remove the brown manganese dioxide, so long as it is completely washed out afterwards, but sometimes, and even after thorough washing, wool and silk treated with sulphurous acid will acquire a yellow tint in a little time. For these fabrics, it is better to substitute for sulphurous acid in the process a weak solution of hydrogen peroxide acidified with a little acetic acid. A solution of oxalic acid, containing a little acetic acid, will also remove the brown colour, but it requires a longer time to act, and in the case of very marked stains, some difficulty may be experienced in getting rid of the last traces of brown colour.

When a stain is a very bad one, it is not advisable to leave the fabric for a long time in the solution of permanganate in the hope that prolonged oxidation will remove it. It is far better to repeat the whole process, as in this way obstinate stains, such as the marks of a scorch, can be removed with the least possible damage to the fibre.

If the precautions mentioned are carefully observed, this method of bleaching will be found to be a very useful one in laundry practice. It is, perhaps, a little more troublesome to apply than a chlorine process, and the smell of sulphurous acid is somewhat choking, but the chance of damaging fabrics is very much less, while the solution of sulphurous acid may be diluted and the browned fabric left in it a longer time to decolourise.

Of the other bleaching agents mentioned in the list, hydrogen peroxide, sodium peroxide, and sodium hydrosulphite are probably the only ones of any special interest. There is reason to believe that both in the bleaching which occurs with light and in that which is observed to have taken place after exposure of soaped articles on grass during nights of heavy dews or white frosts, or on the surface of snow, hydrogen peroxide plays an important part. This substance is generally obtained in the form of a solution in water described as a 10 or 20 volume solution which will often be found to be slightly acid in reaction. A 10 volume solution means one which would give a volume of oxygen 10 times greater than the volume of liquid from which it was obtained if all the available oxygen in the hydrogen peroxide (H_2O_2) present were expelled. Such a solution contains about 3 per cent. of real H_2O_2. It can be obtained of higher concentration than that represented by 20 vols., but as with increased strength the solution as commercially prepared becomes more unstable it is not advisable to keep any quantity of greater strength than the 20 volume solution. Perfectly pure H_2O_2 in solution is remarkably stable but when impure it decomposes into water and oxygen. This change is much accelerated by the addition of alkalies. Traces of free acids on the contrary retard the decomposition and enable solutions of the strengths mentioned to be kept practically without any great alteration for a considerable time.

As a bleaching agent, hydrogen peroxide is slow in action. For use with wool or silk, the 10 volume solution may be diluted 10 times, and its action will be hastened if enough very dilute ammonia is added to make the liquid faintly alkaline. The articles to be bleached may be left in this diluted solution for from half an hour to one hour. They should then be hung up to dry somewhat slowly in the air and in as much light as it is possible to expose them to. If the bleaching is not satisfactory, it is better to repeat the soaking and drying, as in this way more effectual bleaching is obtained than by leaving the articles soaking for a long time in the peroxide solution.

Sodium peroxide (Na_2O_2) is sometimes used as a substitute for hydrogen peroxide or as a source of this substance. If sodium peroxide is mixed with a little water there is a brisk disengagement of oxygen with the formation of caustic soda, but if it is added to a considerable volume of cold water, it dissolves without noticeable evolution of oxygen, and the solution behaves as an alkaline solution of hydrogen peroxide. It is doubtful whether the use of sodium peroxide offers any advantage to the launderer, but should he wish to employ it, a solution containing ·7 per cent. of Na_2O_2 (about 500 grains to the gallon) will furnish about the same amount of available oxygen as the dilute hydrogen peroxide mentioned above. It must, however, be specially remembered that such a solution will be alkaline to an extent equal to one of caustic soda, containing almost the same amount of NaOH, viz., ·7 per cent, and it has been stated already that anything like such a strength of caustic alkali would seriously affect wool and silk. To overcome this difficulty, magnesium sulphate is added, so as to form sodium sulphate, and

comparatively innocuous magnesium hydrate and possibly a little peroxide. If magnesium sulphate ($MgSO_4 \cdot 7H_2O$) is added to an amount which is three times that of the sodium peroxide, the liquid will be practically free from any caustic soda. Another way to avoid any caustic soda and to produce a solution of hydrogen peroxide ready for bleaching, is to add dilute acid to the ·7 per cent. solution of Na_2O_2 until it is nearly neutralised, or what is safer and easier to just acidify the solution, and then to render it faintly alkaline with very dilute ammonia.

Sodium hydrosulphite ($Na_2S_2O_4$) has been mentioned on account of its value as a bleaching agent for one purpose specially. Among the blues which are used to correct any yellow tinge on washed articles methylene blue has a marked affinity for cellulose, which it dyes with a colour which is very fast to most bleaching agents, and if the blueing has been overdone it is very difficult to remove it with the ordinary bleach without damage to the fabric. A dilute solution of sodium hydrosulphite (about 1 per cent. will suffice) will rapidly whiten the dyed material. The colour will return on rinsing and exposing to air, but to an extent only of about 50 per cent. of the original depth of colour. A second or third immersion in the solution of sodium hydrosulphite, with good rinsing in between, will probably bring the colour to the right hue without any fear of affecting the fibre prejudicially if thorough rinsing follows the bleaching.

In conclusion, it may be permitted to remind the launderer once again that bleaching of any kind should be resorted to as seldom as possible, and to suggest that he might well make it his business to educate his public to understand the impossibility of removing either bad stains, or very excessive dirt, in the time given to him, without employing a treatment rather more drastic in character than that which is involved in the use of soap and water alone.

MOHAIR INDUSTRY OF KONIA.

The following report on the mohair goats of the Konia district, drawn up by the Acting British Vice-Consul there (Capt. Doughty Wylie) is taken from the *Board of Trade Journal*:—

By the last returns of the "agnam" tax for 1906, there were then in Konia province 566,100 mohair goats alive, not counting this year's kids. Of these, the severe winter and spring of 1906 and 1907 have killed about 30 per cent. Of this loss, it is estimated that 15 per cent. were males, 40 per cent. females, and the rest yearlings. They died from wet, weakness induced by starvation, and from abortion. However, about the same quantity of mohair is on the market this year as last year, most of the dead goats having been clipped after death. The general quantity of mohair from the Konia market is about 200,000 okes (oke = 2·83 lb.), of which 145,000 okes have gone already to Constantinople.

The quality this year is below the average. The hair of dead goats cut off in the winter is neither so long nor so strong as that of live goats clipped in the spring.

The present year is said to be bad for the following reasons:—

1. The hair of the dead goats has in many cases been mixed with that of the live ones, which brings down the general average of quality. Also where goats were housed in the bad weather, their hair was stained by overcrowding.

2. The winter wet and starvation killed the weaker goats, which are the females and young, and these give the best hair. For this year and next there is left a surplus of older coarser-haired goats, which will again bring down the average of quality.

3. The wet breeding season caused much miscarrying, and the loss of the kids will give a loss of 30 per cent. in next year's clip.

4. The market is congested. The buyers told me in the end of August that there were 24,000 bales accumulated in Constantinople, since when 1,500 only have been sold. They say that the English market is holding back for a better price, and perhaps is distrusting this year's quality; that the American buyers are taking the place of the English, but that they (the buyers here) expect the price to fall before the stocks on hand are disposed of.

The general tendency of the trade is to increase. The price is one to two piastres (piastre = 2¼d. about) higher than last year. Prices here are calculated at pts. 108 to the Turkish pound, as against pts. 100 in Constantinople. The difference pays the carriage, so that no allowance need be made on Konia prices for cost of carriage to Constantinople. At the end of August prices were in Konia:—

White—Finest, 17 to 17⅓ pts. the oke; second quality, 15 to 16 pts. the oke; third (mixture), 14 pts. the oke. Add 3 pts. for Angora and 2 pts. for Akshehr.

Brown or yellow (Tshellengi)—Finest quality, 14½ to 15 pts. the oke—deduction made according to percentage of bad hair mixed.

The white mohair is best in the Kastamuni and Angora districts. In the Konia district it is found along the hills from Konia to Akshehr, and in the next vilayet at Karahissar and neighbourhood. Towards Nigdeh there are some tiftik goats, but I think they are mostly brown. Towards Seidishehr and Beyshehr, the majority of goats are black, and very little white tiftik comes from there. Within eight

hours from Konia the best villages are Mabass, Baghri Kurd, Meidan, Biledjik, Bashara Kavak, Kourshoumli, Tal Kenyi, Aahriz, Silleh, Killik Euren, Shandir, and Sismeh.

In Angora and Kastamuni the hair is longer and thicker, but not so fine as nearer Konia. An Angora goat in December, when his hair is at its heaviest, can give five pounds of hair, but in Konia only three. The weight of a bale of Angora mohair will be 70 to 75 okes, one of Konia mohair only 60. The length of Angora mohair might be put at 6 ins., as against three for Konia. As is natural with the shorter hair, Konia mohair is thinner and finer. The price rises, however, with length and weight, and is progressively higher from here to Karahissar along the Anatolian railway.

The reason of the difference in quality appears to be that while at Konia the hills are bare of trees and bushes, further on they are covered with "meshellik," an oak shrub. The goats feed freely on this (they will eat nearly everything), and thus it secures them both pasture and, what is equally important, shade in the summer. After the clip, in particular, hair grows longer and quicker in cool, shady places than on bare, hot hills.

I hear that at Karahissar some trouble is taken to feed the goats in the winter, and to prevent in-breeding. Here there is practically nothing done. Occasionally in wet weather the goats are housed, but in such a case they are enormously over-crowded, which stains and spoils their hair, and they are not fed. From time to time they are driven out to pick up what they can, which, if there is much snow, is very little. Black and brown goats stand the winter better than the white ones, which are more delicate even than sheep. Wet is their greatest enemy, especially after shearing, and in the breeding season, when it causes abortion. Here breeding is left very much to chance. There is a curious power in the white stock when crossed with the brown. Thirty years ago there were no white goats in Konia, but now there are many. The first cross with a white male produces a white kid with slight brown markings. The second cross is pure white. The females drop their young (usually one) in March.

The clip takes place at the end of April, about ten days earlier than with the sheep. Males are clipped first, to give the females more time after kidding. The kids are not clipped, as are the sheep, in the autumn of their first year. A black goat gives about 1 lb. hair (not exported), a brown $1\frac{1}{2}$ lb., a white 3 lb. in Konia, 5 lb. in Angora. A young goat gives no hair his first year, but after that for 12 or 13 years gives a good clip. From then onwards, though he may live for 20 years, his hair deteriorates every year. Females and young give the best hair. Mohair is never washed before export, whereas wool always is.

The Cape goats do not give such fine hair as those of Anatolia. There is no winter there comparatively, and the hair does not grow so well. There is a great want of Angora blood, and if the export were not forbidden a male goat would fetch £100 or more. In California there are now between 300 and 400 goats, but no thoroughbreds. There also there is a great want of Angora blood, a male goat having fetched 1,000 dollars.

Mohair pays 480 pts. a ton to Haidar Pasha, and 10 pts. for quay dues. There is no rebate given on a quantity. Buyers complain that they pay here at the same rate as at Kutahia and Karahissar, no reduction being made proportional to the distance.

DECORATIVE ART IN GERMANY.

All trades, dependent more or less upon gratifying the demands of taste and the æsthetic sense, are liable to fluctuations, following the gradual alterations in general standards of art, and the more variable whims and caprices of fashion, and one of the German industries affected in this manner is that interested in the manufacture of minor accessories of the upholsterer and house decorator and several closely connected trades. A very marked change in the general character of interior decoration has occurred during the past few years in Germany. The present school of architects, painters, decorators and designers, is aiming at artistic effects in which simplicity is the dominant note. The present demand is for symmetry and grace of outline, and broad even surfaces with effective chromatic harmonies, but discards the mass of minor accessories and the elaborate detail which have hitherto characterised the treatment of a German interior and the art of the upholsterer. This change, according to the American Consul at Chemnitz, was strongly pronounced last year in the exhibits of furniture and decorative designs at the industrial exhibitions held at Nürnberg, Yurikan, and other places, and especially at the exhibition of German industrial art in Dresden. At the latter there were exhibits of over one hundred completely furnished rooms. Nowhere were fringes, tassels, galloons, or the like visible. Woodwork was almost invariably smooth and but rarely touched by the carvers' tools. The change in public taste is so marked that it has affected several well established Saxon industries so seriously that the Government has felt compelled to carefully consider the situation and ascertain whether any measures can be taken to relieve the stagnation in the group of trades directly involved. The Minister of the Interior recently called upon the Chemnitz Chamber of Industry for a full report upon the matter, together with its recommendations. Chemnitz, like other German cities has, in addition to its Chamber of Commerce, also a Chamber of Industry—Gewerbe-kammer—directly representing in the productive industries both capital and labour. The Chamber has recently communicated its report to the Minister, and the following is

a summary of its conclusions. In regard to such upholsterer's accessories as are produced by a branch of the so-called passementerie manufacture, there is no question on the part of the trade but that the tendency of modern art is completely opposed to the further utilisation of their creations. This is strongly marked in the costlier forms of furniture, less so in the cheaper forms. The chief cause is the demand for smooth, even surfaces, in harmony with the prevailing canons of taste. In the category of less expensive furniture, the unwillingness to pay present prices for trimmings of good quality, has limited the use to some extent. Upholsterers complain that heavy fringes, tassels, and similar accessories, which formerly gave them much remunerative employment now are completely banished, or are replaced by modest, inexpensive edgings. Until recently, they were frequently called upon to undertake complicated designs of folded stuffs in the interior decorations of rooms, which involved preliminary sketches, and a high grade of artistic ability in the execution of the plans. The present style of decoration calls for simple materials, free from folds, with a limited amount of embroidery, which are found ready made in shops, and involve no special ability in arranging. Plaster decorators, and wood carvers and turners, state that their trades have all suffered seriously from the prevalent fashion for smooth surfaces on furniture, and in decorative architectural features. The Chamber has appointed a special Commission of experts to study the case, and the opinions of the members of this Commission are worthy of note. One member, an architect and professor in the technical college, declared that from the hygienic standpoint he was strongly opposed to any return to former styles, and in favour of extreme simplicity in all furnishings. Another member, the president of the Industrial Art Society, emphasised the fact that the modern decoration methods meant more light, and a free movement of air in the home than was formerly the case. Further the new movement had lifted German decorative art from a condition of stagnation, and it was now able to meet competition in the world's markets. It was to be regretted that it involved temporary loss for a group of trades, but the future development would soon offer work for the workpeople now so seriously affected. The Commission was, however, unanimously of the opinion that the tendency towards simplicity was being overdone, and was in danger of becoming a fad rather than a healthy, artistic development. Symptoms of the reaction appear to be already visible. The older patterns are now favoured in the orders given for the choicest kinds of silk stuffs employed in upholstery. There is a falling off in the demand for perfectly smooth and even articles of furniture. Projects for intervention on the part of the Government, by offering prizes for designs in harmony with the older fashions, and by influencing the courses of instruction in the schools of industrial art, were rejected as unwise and useless. It was regarded as entirely outside the province of an administration to attempt to stem or guide movements which concern exclusively questions of public taste and fashion, and to intrude into the domain of æsthetics. This recommendation will no doubt be followed by the Saxon Government. In the present state of unexampled prosperity in most of the industries of Saxony, especially in the textile branches, the classes of workmen affected by these changes will, it is said easily find occupation. At present, however, they are inclined to treat the apostles of "the simple life" with scant courtesy.

THE PROGRESS OF JAPAN.

Writing three years ago upon the commerce and industries of Japan, the president of the United Chambers of Commerce, Baron Elichi Shibuoawa, said there are four peculiarities in the Japanese character which make it hard for the people to achieve business success. "These are: Firstly, impulsiveness, which causes them to be enthusiastic during successful business, and progressive, even to rashness, when filled with enthusiasm; secondly, lack of patience, which causes easy discouragement when business is not so successful; thirdly, disinclination for union; and fourthly, they do not honour credit as they should—that which is so important a factor in financial success." However that may be, the commercial progress of Japan since the war has been very marked. As a result of the war Japan's commercial interests are largely extending southward through China, westward through Korea and Manchuria, and northward to Siberia and Saghalin. The three great ports of Yokohama, Kobe, and Baku, though not geographically in closest proximity to the countries named, in 1906 dealt with seven-eighths of Japan's exports, as they did in 1903 and in 1896. The commercial centre of gravity has not shifted, but the course of events is infusing new life and activity into the extremities of the Empire, as indicated by the rise in the value of exports from all other parts of Japan combined. The value in 1896 was about £1,500,000; in 1903 it had risen to nearly £3,500,000, and in 1906 to the considerable sum of £5,348,346..

In his report on the trade of the Consular District of Yokohama, just issued (Cd. 3283), Mr. Acting Consul-General Hobart-Hampden gives it as his opinion that the import of cotton goods will soon be insignificant. In 1906 they were of the value of £1,103,461. The Japanese mills are more and more able to cater for local requirements, and there is no doubt in Mr. Hobart-Hampden's judgment that in the near future ordinary grey goods will follow the case of T. cloths and of 7 and 8¼ lb. shirtings, and be exclusively manufactured in Japan, although a few pieces of the foreign better class 9 lb. may continue to have a certain vogue for some years. On the other hand, Japanese weaving establishments are not yet capable of turning out cambrics or general shirtings,

and it is thought that there will be an increased importation of such cloths for some time. 1906 will be remembered in consequence of the extreme prosperity of the spinning and weaving industry in Japan. Profits were enormous, and a large increase in the number of spindles is the result. In addition to this increase several new companies have been started, and the expansion is likely to continue for another year, since early deliveries of machinery could not be obtained. The mills are well sold ahead, and have contracts which will keep the spindles busy for some time to come.

Raw and waste silk was exported in 1906 to a value of £11,729,763, manufactured silks of £4,070,172, together £15,862,935, silk exports representing 77 per cent. of Yokohama's total exports for 1906, a fact which illustrates the paramount importance of this branch of Japan's export trade. The following figures, in bales, give the total exports of raw silk for the years indicated, and its distribution:—

QUANTITY IN BALES.

	1902.	1905.	1906.
To America	48,467	52,755	73,775
,, Europe	28,787	18,278	28,832
Total	77,254	71,063	102,607

With regard to the quality of the present season's silks Mr. Hobart-Hampden says that it may be classified as a medium one, and considering that owing to climatic conditions cocoons have been, generally speaking, exceedingly good, it cannot be said that reelers have taken special care to improve their goods. The Japanese Government, however, is doing its best to improve and develope the silk culture and reeling processes by creating special schools for the perfecting of rearing and reeling, and the Consul-General reports a steady improvement in both directions, "although this improvement may not as yet have made itself distinctly apparent throughout the trade generally."

The following table shows the share of the principal participating countries in the imports and exports of Yokohama:—

VALUE.

Country.	Imports.	Exports.	Total.
	£	£	£
British Empire	6,498,099	2,919,441	9,417,540
China	1,257,821	1,309,327	2,567,148
Germany ..	1,856,988	325,942	2,182,930
United States	2,801,585	10,571,514	13,373,099

Of the total trade with the British Empire, £6,151,429 went to the United Kingdom, and £1,894,941 to India. The only British possession to show an advance was Canada, for which flour partly accounts. It may be noted that Yokohama's trade with the United States exceeds that port's trade with the British Empire by £1,158,974; but this, says the Acting Consul-General, "is merely a striking instance of the danger of quoting from the figures of a particular district. In point of fact, the trade of Japan as a whole with the British Empire in 1906 exceeded her exports to the United States by no less than £11,854,330, while the imports from the United Kingdom alone fell short of the exports to the United States by little over £2,500,000." It would have added to the value of Mr. Hobart-Hampden's report if he had explained how it is that the exports to the United States from Yokohama are so large as compared with the total exports of this country to America.

Mr. Hobart-Hampden says that Japan is at present averse from widening openings for foreign imports. Aided by a high statutory tariff, once more raised from October 1, 1906, designed primarily for revenue purposes, but also designedly protective, she aims on the one hand at cutting down her bill for imports, which in the year under review were exceeded by exports, and on the other hand at becoming not only her own supplier of manufactures, but also in an increasing degree the supplier of the markets of the Far East. Her efforts in this direction are being attended with success. Comparing 1896 with 1906, her exports to China have increased from £1,470,236 to £12,023,327; to Korea from £332,078 to £2,573,500 to Siam from £1,045 to £24,027. But if there is a desire to restrict foreign privileges there is willingness to invite the co-operation of foreign capitalists in large enterprises for the exploration of the natural resources of Japan, and the development of her industries. "Japan has already become the great industrial country of the Orient. She has a good asset in a considerable supply of water-power of which she is now availing herself, while her proximity to her Eastern markets, and the support of a Government unsurpassed in the methods of encouraging external trade and organising systematic competition, place her in a favourable position. At the present period of *post bellum* restlessness, excessive speculation, and company promoting, prudence is necessary; but i there is a disposition to narrow the avenues of approach for imports there may, perhaps, in a few directions, and in individual instances, be some room for a cautious participation of British energy in the growing activities of the country. Still at best profitable occasions can only be rare, and the present attitude of welcome may prove to be only a passing phase. What is most needed by Japan is capital. She has already made use of her own capital not only in various private undertakings, but in supplying the needs of the State. The only way by which it will be possible to go on with various enterprises is to import foreign capital, but if that is to be got the barriers must be removed, such as the restriction of the ownership of land by aliens, the limitation placed by the Railway's Act upon the pledging of railway properties, and other prohibitions of foreigners as regards mining, &c. Something has been done in this direction since the war, but more remains to be done.

ARTS AND CRAFTS.

Batik Work.—In view of its great popularity on the Continent, it seems rather odd that we never see any Batik work in England. It is not that we have never heard of it; the magazines devoted to art take good care now-a-days that what is done in the remotest corner of the civilised world shall be known all over the globe—and Batik work is no exception to the general rule. And yet, the fact remain. One may go to a dozen Arts and Crafts or Home Art Exhibitions here in England, and see no example of the work, while abroad it has become sufficiently popular to find a place in schools of art, and to be imitated by enterprising German manufacturers. It was, of course, only natural that it should be taken up primarily in Holland—for Batik work, as we most of us know, had its origin in Java, which is a Dutch colony. The production of such work by European art-workers is more or less the outcome of the desire on the part of Holland to push the products of her own colonies. One would have imagined that, in a country like our own, where the search for new art crafts is so persistent, any fresh suggestion would have been eagerly welcomed. But, as regards Batik work, this has not been the case. That may be partly because cotton printing is such a highly developed industry with us that any craft which competed, however remotely with it, seemed doomed to failure. Or, again, it may be because our English would-be craftsmen and craftswomen are more impatient than their Continental brethren, and prefer to spend their time on processes which either show more results for their labour or do not take so much care in production. For all that, it would appear that they might do worse than take to Batik work. The method is the hand worker's way of doing what the manufacturer does by discharge or resist, to which last it is more naturally allied. That portion of the material which is not to be coloured is coated with wax, and the whole thing is then put into the dye pot. When it comes out, the uncovered parts of the material are found to be dyed blue, or brown, or whatever it may be, while the wax has prevented the colour from penetrating to those portions of the design which it covers. Not entirely, however, for it constantly happens that the wax cracks, or partly cracks in places, and lets the colour through in fine cobweby lines, producing sometimes an effect rather like marbling over the whole, or part of the design. This may not be altogether commendable as workmanship, but it often helps the colour effect of the work pretty considerably, and is artistically really one of its charms. The colours most commonly employed in European work are brown and blue, and a certain amount of red, but the examples which come from Java are sometimes partly executed in a rich dark green colour, which seems as if it might have been produced by the combination of blue and brownish yellow. Though Batik work is most commonly executed in cotton, it is often done on silk, and it is also carried out on parchment and on soft leather. The work done in the West Indies, where presumably time is of little or no value, is often very intricate, but that which is executed in Europe is a good deal simpler in character. There is, of course, nothing new about the process, but its results are sufficiently unlike those of ordinary printing to be at once striking and suggestive.

Embroidery and Costume.—The fashion of historical pageants, in which the dresses of the actors are decorated after the manner of a byegone age, and the present taste for embroidered dresses, wraps, coats, &c., have together been taxing the ingenuity of those who devote themselves to the less serious kinds of embroidery. The demand, of course, is met in a great measure by work produced by the sewing machine. Such embroidery is naturally mechanical and does not look altogether satisfactory when it is too closely inspected, but it is effective enough in its way; it is turned out very rapidly, and it can be executed on velvet with apparently much more ease than handwork—in the case of which the pile often gives a good deal of trouble. One's natural feelings are, of course, all against this machine embroidery, but the work so produced has undoubtedly greatly improved of late; and for the decoration of ordinary skirts and o pageant dresses which will presumably only be worn a few times and have only to be seen from a distance, it strikes one as absolutely wasteful to employ anything like fine hand work.

Another and more satisfactory kind of work which is encouraged by the prevailing fashion is that of simple designs executed entirely in couching. In the finer work gold thread, thick silk, or thin cord are used, while in the coarser a quite heavy cord, or even a fine braid, is sewn down. In this type of embroidery more depends upon the skill of the designer than upon that of the embroideress. Such simple couching is easy of execution to anyone who has a reasonable knowledge of her trade—the essential thing is that the lines of the design should be sweet and that its general distribution should be pleasing. What is wanted is not so much very great accomplishment as reasonably good taste together with a knowledge of what can be quickly executed and of what will tell in the finished work. It is occasionally desirable that this outline work should for the sake of emphasis be associated with a little solid work, perhaps with touches of *appliqué*. When, however, this latter, instead of consisting of stuff laid flat on the ground, is arranged in pleats or gathered, or ruckled up, rather after the manner of a kind of glorified ribbon work, the effect leaves a good deal to be desired, for it completely destroys what dignity there may be in the design and takes away all feeling of restfulness. When the ornamentation takes the form of natural flowers standing out in high relief and made of pieces of silk or satin only attached in places to the material of the garment, we feel that, to all intents and purposes, the embroidress has given place to the milliner.

It is, by the way, satisfactory to note that some of

the societies for the encouragement or sale of needlework are turning their attention to the production of embroidered cuffs, revers, &c., which are simple and unpretentious in design and, though effective as need be, can be executed without an undue amount of labour.

Applied Art and Economics.—Questions of industrial art have a way of verging on economics. That is only natural when we consider how closely that part of applied art, which in the long run tells most, is allied to manufacture and trade. There are, of course, a good many people who see in this close connection between art and manufacture only something to be deplored, but the combination is in the main for the good of both parties. There are times, however, when the outsider, and even the insider so far as the workman is concerned, allows it to obscure the point at issue. Just now, for instance, there is an outcry against the conditions which prevail in the homework trades carried on in the slums of London and other great cities. There is also a good deal of talk, and a good deal of experiment, going on about the establishing of art crafts in the country and under ideal conditions of employment. Undoubtedly the outcry in the one case is sadly needed, and the ideal in the other is altogether admirable. That much must be admitted with sincerity by all fair-minded persons. But there is absolutely no guarantee that work executed under perfect economic conditions will be good art, or even good workmanship. Indeed, I think we could most of us recall, with but little reflection, work so executed which left much to be desired. And on the other hand, work done in uncongenial surroundings, though not likely to rise to a very high level of art (if the executant is responsible for its design) is not necessarily bad in workmanship. To make match-boxes at, say, 2¼d. a gross in a small and, perhaps, insanitary room is not a life which can be considered in any way right or desirable. The existence of such a state of affairs would seem to the ordinary mind to prove rather that it would be better to make such things by machinery, than to support the case for the beauty and dignity of hand labour. That other workers under other conditions can produce beautiful work does not conclusively prove that these particular workers could do anything of the kind. We have, however, ample evidence that a good deal of the so-called "art-work" which is being put upon the market is neither technically nor artistically good. Let us by all means call out against bad conditions of labour; let us try all the experiments we can for improving such conditions; but in the name of logic and common-sense let us abstain from assuming that it is possible to put such things as punnets and match-boxes side by side with wood-carvings, enamels, leatherwork, &c., and talk about "the contrast between work that *ought* to be done and would be done under a wise system of government, and the work that unfortunately *has* to be done under present conditions."

CORRESPONDENCE.

THE MOTOR-CAR TRADE IN THE FAR EAST.

Mr. Gordon E. Greig, of Raub, Pahang, Federated Malay States, writes respecting the article on "The Motor-car Trade in the Far East" (August 23rd, p. 969):—

Both in Singapore and the Federated Malay States solid tyres have been tried (*not* Clincher, which are pneumatic) and found wanting. I do not think there is a single solid-tyred car in the Federated Malay States now, except a few old Albions and a motor service of Albions. Four-cylinder cars and single-cylinder De Dions and Rovers are the favourite cars.

A very large number of cars are fitted with magneto ignition; in fact, *all* the larger cars are, most with dual ignition; and, although I am not so *au fait* with the Singapore cars, dry batteries are almost universal elsewhere. All lubricating oils come from home.

The statement that air-cooled motors are not a success is unfounded. I have ridden air-cooled machines now for three years, from 2-h.p. to 5½-h.p. twin, and I have never experienced over-heating, so-called, even when towing a trailer for 35 miles on one of the real hot days, with a 3-h.p. engine.

As to the radiators upon water-cooled engines remaining hot for days at a time, the temperature never rises above 95°, and falls below 80° at night. Surely twelve hours is enough for any engine to cool down.

As to railways, there is one across Singapore. Another from Malacca town right through to Penang. Another from Port Swettenham to Khala Lumpor. Another from Port Dickson to Seremban.

Motor-cars are exceedingly useful and popular, and in Perak and Selangor are used to a very great extent by the Europeans both in the Government, and out. In the Federated Malay States, at least, the Chinese do not use their cars very much, as they have not the travelling to do that the Europeans have, and do not care, as a rule, to travel over the country, with a few exceptions.

[The statements in the article referred to were all made on the authority of the American Consul-General at Singapore. From independent inquiries made in this country it appears that solid tyres (Clincher tyres are made in both the solid and pneumatic form) are now being shipped to Singapore. The success or non-success of air-cooled motors may be regarded as a matter of opinion. A competent authority in London confirms the view expressed in the article. Of course the opinion expressed referred to motor-cars, not to motor-bicycles, from the use of which, to judge from the context, Mr. Greig's experience seems to have been derived.]

OBITUARY.

Sir Charles Arthur Turner, K.C.I.E.—Sir Charles Turner, late Member of the Council of India, and formerly Chief Justice of the Madras High Court, died at his residence in Ennismore-gardens, on the 20th inst. He was born at Exeter in 1833, and from the grammar school of his native town he went to Exeter College, Oxford, where he graduated M.A., and was elected to a Fellowship in 1855. At the age of twenty-five he was called to the Bar (Lincoln's-inn), and went the Western Circuit. In 1866 he was appointed Judge of the High Court of the North-Western Provinces of India, now the United Provinces. He acted as Chief Justice in 1870, 1875 and 1878. The writer of the obituary in *The Times* says, "A man of strong feelings and warm heart, Turner may not have had the typical judicial temperament. Yet he was eminently fitted for the preferment to the Chief Justiceship of Madras, which came in 1879. Not only had he facility for laying his finger on the vital points of a case; he was also skilful in the work of organising and supervising mofussil establishments, and in drafting, quickly and clearly, High Court orders and notifications. Moreover, his unusual physical strength was unsparingly devoted to the public service. He revelled in the subtle intricacies of Indian law and custom; and he gave every encouragement to the local Government in the habit of referring complicated questions of administration or proposed legislation to the High Court. He speedily mastered the salient points of large schemes or systems, such as the local revenue administration, which was quite different from what he had been accustomed to in Allahabad, and the abstruse customary law of Malabar and the West Coast." He was Vice-Chancellor of the Madras University in 1880 and 1882. He retired from the Bench in 1885, and became a member of the Public Service Commission. Returning to England in 1886, he was selected two years later by Lord Cross to fill the judicial seat on the India Council. He served for the statutory period of ten years, and was Vice-President of the Council in 1896-7. He was created a K.C.I.E. in 1879.

Sir Charles Turner was elected a member of the Society of Arts in 1890. He was a member of the Indian Section Committee, and presided and spoke at the meetings of this section on several occasions.

GENERAL NOTES.

Smyrna Carpets, Dyes and Colours.—In the course of his report upon the trade and commerce of the Consular district of Smyrna (Cd. 3727-4) Mr. B. A. Altintop, of the British Consulate-General, refers to the dyes and colouring substances used in the Smyrna carpet industry, and says that nearly all are imported from Germany and France. The information given to Mr. Altintop by the head of one of the most important local British manufacturers of carpets is that the German and French dyes are both better and cheaper than similar British products. The German manufacturers either visit the district personally or send their agents, who penetrate into the chief centres of the interior where carpets are manufactured, show their dyes to the men, or teach them how to employ them. The British manufacturer, or his travellIng agent, is never, according to this authority, seen in Smyrna. As for the samples and patterns contained in a book published by a dye manufacturing firm in the United Kingdom and sent to a carpet manufacturer, the same authority affirms that most of the dyes of which samples are given are German dyes imported into the United Kingdom. The same authority gives also the names of two German manufacturers who had personally visited Smyrna and the carpet industry centres in the interior, and had established solid business connections. A certain amount of nature-colouring substances, such as valonea, yellow berries, madder root, &c., have also to be used in subduing colours, &c. Indigo (natural) until a few years ago used to be imported exclusively from India, but within the last few years German synthetic indigo has been replacing the natural article.

"Tunbeki" Tobacco.—Ispahan is the great centre of "tunbeki" tobacco cultivation, a class of tobacco practically unknown in the United Kingdom. It is not adapted for use either in the form of cigarettes, or of pipe tobacco, but is consumed exclusively in the Persian kaliûn, or Turkish narghillé (water-pipe). Though in more or less general use all over Asia Minor and Egypt, the Ispahan product is for the most part consumed in the Mediterranean littoral. Smyrna, with its dependencies, is an important consumer, but Beyrouth and Syria generally come first. Tastes differ, says Mr. Consul-General Barnham, in referring to the matter in his report on the trade of Ispahan and Zezd (Cd. 3727-6), in these two districts, the former preferring the light coloured and milder leaf, which is much stronger. Egypt is also a large consumer, and there, as well as in Turkey, the importation is in the hands of a monopoly. A less important market is Greece which, however, of late years has started growing this article. The United States take a small quantity, probably for the use of the many Greeks and Syrians who emigrate to that country. Syria also produces an inferior quality, grown from seed originally imported from Ispahan. Mesopotamia and the Red Sea littoral do not consume the Ispahan plant; the former takes that grown near Shiraz, and the latter, that produced in Laristan. This latter is shipped principally from the port of Lingah. Constantinople and the Black Sea littoral consume very little of the Ispahan plant, using instead the Kashan tunbeki, which is packed after being saturated with brine.

FRIDAY, NOVEMBER 1, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

COLONIAL SECTION COMMITTEE.

A meeting of the Committee of the Colonial Section was held on Tuesday afternoon, 30th ult. Present: Sir Westby B. Perceval, K.C.M.G. (in the chair), Byron Brenan, C M.G., Hon. Sir Charles W. Fremantle, K.C.B., Robert Kaye Gray, Arthur H. Reid, Sir William Hood Treacher, K.C.M.G., Sir Frederick Young, K.C.M.G., with Mr. S. Digby, C.I.E., Secretary of the Section.

VIVA VOCE EXAMINATIONS IN MODERN LANGUAGES.

During the present year 21 examinations have been held in London, Manchester, Bristol and Guernsey.

At these examinations 629 candidates presented themselves, of whom 476 passed (75 with distinction) and 153 failed. The languages taken up were French, German and Spanish.

The results of previous years are as follows:—

Year.	Number Examined.	Passed.	Failed.
1902	280	202	78
1903	456	324	132
1904	540	375	165
1905	681	502	179
1906	644	469	175

The following is a complete list of the *Vivâ Voce* Examinations held during 1907:—

Place of Examination.	Date.	Number of Candidates.	Passed with Distinction.	Passed.	Failed.
French:—					
Tottenham Polytechnic	March 18.	54	1	39	14
Willesden Polytechnic..	March 19.	27	1	19	7
Acton and Chiswick Polytechnic	March 20.	16	2	10	4
Guernsey Education Committee	May 16.	23	2	17	4
French (*continued*):—					
City of London College (Candidates from London Polytechnics)	June 10.	39	2	27	10
Regent-street Polytechnic (Candidates from London Polytechnics)	June 11.	36	2	26	8
Manchester Education Committee	June 20.	16	4	8	4
"Barnsbury Park" L.C.C. School	June 24 & 25	57	6	45	6
L.C.C. Evening School, Essendine - road, Maida-hill	June 25.	11	—	8	3
L.C.C. Evening School, Sussex-road, Brixton	June 26.	18	2	14	2
L.C.C. Evening School, Blackheath - road, Greenwich	June 27.	25	2	19	4
L.C.C. Evening School, Plough-road, Clapham Junction	June 28.	38	5	27	6
Merchant Venturers' Technical College, Bristol	July 9 & 10.	97	4	65	28
German:—					
Tottenham Polytechnic.	March 22.	18	2	8	8
Birkbeck College (Candidates from London Polytechnics)	June 12.	46	16	18	12
L.C.C. Evening School, Hackford-road, Brixton	June 19.	19	8	8	3
"Barnsbury Park" L.C.C. School	June 20.	22	7	9	6
Manchester Education Committee	June 21.	5	1	3	1
Merchant Venturers' Technical College, Bristol	July 15.	39	4	18	17
Spanish:—					
Manchester Education Committee	June 17.	5	2	3	—
City of London College (Candidates from London Polytechnics)	July 2.	18	2	10	6
		629	75	401	153

The following are the examiners' reports:—

French.—457 candidates were examined. Of these 33 passed with distinction, 324 passed, and 100 failed. The number of candidates examined this year was slightly in excess of the total of last year's Examination. Few failures arose through defective pronunciation. In this respect last year's standard was fully maintained. Whilst several exercises in dictation were

faultless, and a tolerably large number virtually perfect, many failures were attributable to weakness in this part of the work. In conversation, the candidates for the most part acquitted themselves very creditably, and instances of brilliancy were by no means rare. The general impression produced by the examination was distinctly favourable. One of the most gratifying features was the keen interest manifested by the students in their work. The value of an oral test in a modern language is great, and the importance of having some such proof of knowledge is gradually becoming more widely recognised.

German.—149 candidates were examined. Of these 38 passed with distinction, 64 passed, and 47 failed. The number of candidates examined was larger than in any previous year. The percentage of passes showed a slight increase; that of distinctions a slightly greater one. The feature of this year's examinations was the comparatively high number of really excellent candidates who did first rate work in all parts of the examination. There were again a number of very weak dictation papers, though only a few who did well in other parts of the examination failed in this. Probably a very few minutes rather more frequently devoted to this exercise would be found of advantage to most students. On the whole the results were highly satisfactory, and showed that a great deal of very sound language teaching is, often most unostentatiously, being carried on in this country.

Spanish.—23 candidates were examined. Of these 4 passed with distinction, 13 passed, and 6 failed. On the whole the result of the examination was very satisfactory. The majority of the candidates expressed themselves fluently and accurately on the various subjects discussed. Their pronunciation was generally good. Several exercises in dictation were nearly faultless, but in some cases it was evident that candicates had not had sufficient practice in writing from dictation. Weakness in this part of the work caused the rejection of a few candidates.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

DETERGENTS AND BLEACHING AGENTS USED IN LAUNDRY WORK.

By Prof. Herbert Jackson, F.I.C., F.C.S.

Lecture III.—Delivered April 27th, 1907.

The use of soap for cleaning purposes is such an everyday occurrence that the question how it acts and what are the reasons for its behaviour as a detergent may seem at first sight to be sufficiently answered by the facts of common experience. The problem is, however, of considerable interest and by no means easy of solution. A chemical and physical account of this well known action of soap which shall offer a full and satisfactory explanation of it can certainly not be given in the present state of our knowledge. So far as the chemical action is concerned, certain facts about the relation of soap to water are known which may be considered to have a definite bearing on its behaviour as a detergent, although interpretations of the facts may vary. If a neutral soap carefully prepared and purified so as to be free from any free alkali or uncombined fatty acid is dissolved in a little hot water to a clear solution, and a considerable amount of cold distilled water is added, there is a marked turbidity produced which is found to be due to the formation of insoluble acid soaps, that is to say, alkaline salts of the fatty acids containing more than one equivalent of fatty acid combined with the alkalies, while at the same time caustic soda goes into solution. Only a small part of the soap dissolved is affected by this change which is frequently described as the "hydrolysis" of soap. As a rough estimate, and dealing with the average strength of soap solutions used for washing purpose, the amount of alkali liberated in this way would not be more than from two to five grains of caustic soda (NaOH) per gallon, a quantity which under ordinary circumstances would speedily be converted into sodium carbonate by carbonic acid present in the water. An experiment to show this formation of traces of alkali may be made as follows. To a small volume of warm and fairly strong soap solution add a drop or two of phenol-phthalein, with which any ordinary soap will give a red colour, and then add very dilute sulphuric acid until the red colour is just discharged. If the solution is now diluted with a considerable volume of distilled water free from any acid, the red colour will be restored to some extent, showing the presence of alkali liberated by dilution.* The extent of hydrolysis varies with different soaps, with the temperature, and with the amount of water added. The accurate determination of the amount of alkali liberated presents some difficulties, and details of the analytical methods to be employed are outside the compass of this lecture, but a general idea

* A more certain way of showing this is to dissolve some soap in alcohol, to filter the solution, and to add to the filtrate a drop or two of phenol-phthalein. If a red colour is produced, add acid until it is just discharged, but if no colour is seen add weak caustic alkali until a very faint pink tinge is seen. On now diluting with water, the liberated alkali will give a full red colour with the indicator.

may be obtained from the numbers given in the following Table. They are from determinations made on specially prepared neutral soaps dissolved in the proportion of one part of soap to 400 parts of water, and show the amount of alkali set free as percentages of the total alkali originally combined in the soaps:—

Soaps.	Temperature.		
	15° Cent. (59° Fahr.)	40° Cent. (104° Fahr.)	90° Cent. (192° Fahr.)
Cocoa nut oil ..	5·8	8·1	8·5
Cotton seed oil..	6·2	7·3	10·4
Palm oil	7·4	8·5	9·6
Beef tallow	6·8	9·1	10·2
Sodium oleate ..	7·1	5·7	4·1

Too much stress must not be laid on these numbers, as it is found that varying the conditions of the experiments will yield somewhat different results, but it may be noticed that, as a general rule, soaps made from the glycerine compounds of fatty acids having a high average molecular weight are more readily hydrolysed than those from fats containing acids which have a lower molecular weight. Sodium oleate differs from the others in being more affected in the cold than at higher temperatures. It would lead too far to go into this subject fully enough to explain what has been done by various investigators on the hydrolysis of soaps, but the broad facts, in addition to those which have been already stated, are that alkali exercises a marked action in preventing the action of water, that neutral soaps dissolve in strong alcohol without apparent change, and that glycerine also somewhat lessens the extent of hydrolysis. Practically there is very little difference between potash and soda soaps in their behaviour with water in this respect.

The recognition of the fact that soaps do undergo a change when dissolved in water has led to the suggestion that their efficiency as detergents may be considered to be partly due to the action of the liberated alkali on the grease which accompanies most dirt. In dealing with alkalies it has been pointed out that the amount of saponification of grease produced by weak alkaline solutions in the conditions in which they are used is very slight, and that their effects are to be attributed rather to their powers of emulsifying fats and oils.

As the property which soap also possesses of making emulsions with grease is increased in a marked manner by the addition of small amounts of alkali, the hydrolysis of part of the soap employed may be, therefore, considered to supply the alkali required to raise the emulsifying power above that which is inherent in the soap alone. If this were all that has to be considered it might be expected that those soaps which are more readily hydrolysed than others would be the best detergents. This appears to be true in a general sense so far as strictly comparable soaps are concerned, that is to say, alkaline salts of fatty acids of the same series, *e.g.*, lauric, myristic, palmitic, and stearic acids, provided equivalent quantities are taken and the temperature of the water is warm enough to hold a reasonable amount of sparingly soluble soaps like sodium palmitate and stearate in proper solution. But it would not necessarily be true to ascribe the rather greater detergent power of soaps derived from acids of relatively high molecular weight to their increased hydrolysis alone, *i.e.*, to the greater amount of alkali liberated by the action of water on them, for these soaps by themselves have emulsifying properties superior to the soaps of lower fatty acids, and also furnish a lather more readily if used under suitable conditions.

Oleic acid, which belongs to another series of acids, furnishes soaps of considerable solubility in water, and potassium oleate is about two and a-half times as soluble as sodium oleate. If equivalent quantities of these and of soaps from other common fatty acids are taken and a number of comparative experiments are carefully made, it will be found that the detergent properties of the oleates both in cold and hot solutions are sensibly the greater. This cannot be attributed to increased hydrolysis, which is about the same as that of some of the others in the cold, and becomes less as the temperature rises; moreover, the same superiority is found using equivalent amounts of the various soaps in solution in strong alcohol. The difference must, therefore, be due to the greater inherent emulsifying and perhaps lathering power of the oleates, and to other properties which will be dealt with presently. With regard to lathering, experience shows that a good washing soap should give a full lather, but this should probably be looked upon as a sign of other useful properties rather than as a necessity in itself.

So far then the behaviour of soap as a detergent has been ascribed to its own inherent power of emulsifying grease aided by that of the alkali liberated by hydrolysis, the dirt being

either carried away clinging to or enclosed in minute oily globules, or more frequently freed from a slight binding coating of grease, and removed separately in the soapy liquor.

No account has, however, been taken of the influence which soap may exert on the state of division of the dirt, an influence which has an important bearing on the problem of washing with soap and water. To consider this it is necessary to make some preliminary remarks about the behaviour of different sized particles suspended in liquids, but without attempting to discuss theoretical questions more than in a very general way, or than is necessary to make clear the meaning of experimental facts.

If a little clay be rubbed up with water and the mixture left to settle it will often be found that a certain amount of turbidity is left in the water, and that the suspended matter will take days to sink. The turbidity can, however, be removed by passing the liquid once or twice through good filter paper. If the same experiment be tried with gamboge, it will be found that although much of the solid can be filtered off, a residual turbidity will be left which cannot be sensibly diminished by repeated filtrations. Under high magnification with the microscope, the filtered liquid is seen to contain minute solid particles which are, however, so small that they pass through the pores of the filter paper along with the water. If instead of filtering in the ordinary way a drop of gamboge fluid is allowed to fall on a piece of filter paper so that as the drop spreads filtration shall take place along the plane of the paper, the minute particles of gamboge are hindered in their movement with the water stream, and, becoming entangled among the fibres of the paper, are left behind the water which forms a colourless ring round an inner patch of yellow gamboge. The particles of gamboge were visible under the microscope, but evidence can be obtained of the existence of solid matter in a state of apparent solution in water which the microscope will not reveal, except, perhaps, in a few cases, and by using special illumination and optical appliances.

A solution of gold (Faraday's gold), which appears of a ruby colour and perfectly transparent by transmitted light, can be made by dissolving 1 grain of gold trichloride in about a quart of distilled water (the double chloride of gold and sodium sold for photographic toning may be used, but does not give such good results), and adding a few drops of a weak solution of phosphorus in ether. The colour developes slowly, and if the vessel was clean and the water pure, the solution will remain without depositing any solid for a long time—in one case for three years. A little common salt solution changes the colour to a bluish purple, and alters the state of aggregation of the gold particles, so that in a comparatively short time all the gold is deposited as a purple powder. If a little of the ruby solution be dropped on to filter paper in the same way as in the experiment with gamboge the coloured gold remains round the centre of the spreading liquid, and the water passes on. By dropping a little of the purple solution on to filter paper soon after the addition of common salt the purple gold is hindered in its movement more than any unchanged ruby, so that the two forms of coloured gold can be seen separated showing that the particles of purple gold were larger than those of a ruby colour, and accounting for the greater rapidity with which they settled out of the apparent solution. Many similar experiments on filter paper can be made with solutions sufficiently coloured to show well. Most people must have noticed the white rim round a stain of wine freshly spilt on a tablecloth. An extract of logwood in distilled water shows it very well, and so also do several other dyes and colouring matters, but the evidence must not always be taken as conclusively proving the presence of particles which can be filtered away in this manner because some colouring matters have a chemical affinity for cellulose, and form compounds with it of a more or less stable kind.

A further experiment with logwood is of interest. Drop a little of the aqueous extract on to a filter paper, and when the spreading has ceased it will be found that dropping water gently on to the stain does not increase its size perceptibly, but that if an alkali such as a weak solution of sodium carbonate be used the colour changes to purple and the stain extends considerably. This appearance is not due merely to the greater ease with which the deep purple colour resulting from the action of the alkali can be seen, but arises also from a real spreading of colouring matter taken up into more perfect solution. Moreover by letting the alkaline solution drop through the paper the stain can slowly be dissolved away. Whether the action of alkalies is to form compounds with the particles of the colouring material of a smaller size than those in which it originally existed, or whether compounds of the dye and cellulose are decom-

posed by alkalies is immaterial for the present purpose of illustrating the use of an alkali to remove a stain. Probably both actions occur. A solution of borax is more effectual in washing out the stains of logwood and many similar colouring matters, but borax undoubtedly has a special decolourising action on such stains apart from its action simply as an alkali.*

Returning for a moment to the ruby-coloured solution of gold, the presence of particles too small to be seen with the microscope may be revealed by passing a beam of light through the solution, and looking at it from a position at right angles to the direction of the beam. The track of the beam will be shown up by reflected light from the gold particles, and will look brownish and opaque, as if the light were being passed through anything but a clear liquid. Many apparent solutions which show the behaviour with filter paper, which has been described, will exhibit the track of a beam of light to a more or less marked extent, but what may be called more perfect or true solutions such, for example, as those of potassium bichromate, and most other coloured salts, or of methyl orange and many other colouring matters, will fail to show the beam of light at all if they are carefully filtered. If such solutions are dropped on to filter paper, the colour will be seen to extend right up to the margin of the expanded stain, unless there is a chemical affinity between the colouring matter and the cellulose of the paper. When the colour is seen to extend completely in this way it will generally be found that plain water is capable of washing out the stain.

It will be gathered from what has been said that the particles which, as solid dust or diffused through liquids or in solution, constitute the origin of dirt or stains that the launderer is required to remove by the process of washing, may vary in size from those almost visible to the eye, through different gradations of decreasing dimensions to particles of such minuteness as to be revealed only by the reflection of light, or to those too small even for this test of their presence.

Leaving the very minute and ultra-microscopical particles, the granules visible under magnification may be considered from the point of view of the conditions which determine or modify their state of aggregation. It is easy to realise that in the case of a fabric composed of interlacing fibres there will be limits to the sizes of groups of granules of dirt, very wide no doubt, within which they may readily be removed; the larger groups falling away as it were in virtue of their size, while the others owing to their smallness can be washed away by streams of fluid penetrating the fabric. But groups held together by grease or otherwise, and occupying intermediate positions in size, might be entangled among the fibres or cling to them to such an extent as to render it practically impossible to set them free unless their size could be diminished by separating their constituent particles more or less completely. To gain an idea of the way in which soap in its action as a detergent brings this separation about it is necessary to return to the microscopical examination of a turbid fluid. An appropriate example to take is the fluid left after washing a very dirty cloth in soap and water. If it be left for some time to allow the coarser dirt to sink it will be found to remain black and thick for an indefinite period. A drop of it placed on a glass slip and covered with a thin cover glass will show under an amplification of about 500 diameters countless minute particles in a constant state of oscillation, the larger forms moving more sluggishly and through shorter distances than the smaller forms, which are seen to dance about with great activity. If such a turbid fluid is hermetically sealed up to prevent any evaporation and no chemical changes occur, the movement will apparently persist indefinitely. Specimens of similar fluids sealed up twenty years ago show undiminished activity, and no doubt many others of much greater age are in existence, while minute particles visible in fluids sealed up in small rock cavities must have been in motion for a period to which no definite limit can be put. All turbid fluids

* This can be seen by taking a weak extract of logwood and adding equivalent amounts of dilute solutions of sodium carbonate, caustic soda, soap and borax to separate portions. Each will give a purple or violet colour, but on standing, or better on warming, the borax solution will become a pale yellowish colour, while the others will still be coloured more or less strongly, the tints varying from purple to a reddish violet, which may become browner on exposure to air. There is some evidence that borax in solution may be hydrolysed to a small extent in the same manner as soap, but the experiments with the latter and with caustic soda on logwood extract show that the action of borax to decolourise the stain is not to be attributed to the liberation of caustic alkali from the borax by the action of water, but to a specific action of borax itself. Hæmatoxylin, which is the source of the colouring matter in logwood, dissolves in water, but more readily in a solution of borax, with which it forms an indefinite compound. A similar relation between borax and the basis of colouring matters allied to that of logwood may exist, and would explain the action of borax to remove stains of such colouring matters.

which do not clear readily when left to settle show this movement in their solid particles to a greater or less extent. This oscillatory motion of minute particles is now spoken of as "pedesis," meaning a leaping or springing; it was formerly called Brownian movement, after Dr. Robert Brown, who first described it in the early part of the nineteenth century. No explanation of a character sufficiently complete to fit all the facts known about pedesis has yet been given.

It is not proposed to discuss the theoretical aspect of this movement here, as even to discuss the difficulties of framing any theory to explain all the facts which have been gleaned about it, would occupy much more time than can be given to this lecture as a whole. But the application to the explanation of the detergent action of soap is of importance and interest, and some of the facts about the conditions for hastening or retarding pedesis, with their bearing on the problem of washing, will be described as briefly as possible. It has already been mentioned that the smaller the size of the particles the more rapid and extensive are their movements. In the case of particles of equal size those having the lower specific gravities move more quickly than such as are of greater density. It was remarked in connection with the ruby solution, of gold that the addition of common salt caused an agglomeration of the gold, and this may now be described as resulting in such a decrease in the rate and extent of oscillatory motion as to enable the larger groupings of the specifically heavy metal to sink through the liquid. It is found as a general rule that solutions of acids, salts and strong alkalies decrease pedesis and favour the collection of separate particles into groups, or cause them to adhere to any larger masses which may be present, and it has been pointed out that all such solutions as have a marked influence in this direction are conductors of electricity, and that the effects of different solutions are roughly proportional to their conductivities. This generalisation may be taken as true in the main, and as applicable to the question under consideration of the best way of ensuring full play to pedesis in the operation of washing. There are, however, some particles, notably those of certain resinous substances, the movements of which are not sensibly hindered by solutions of great electrical conductivity. The following experiment made under the microscope will illustrate the manner in which pedesis comes into play as an important factor in the removal of dirt. A few fibres from a very dirty piece of linen were placed in cold distilled water under the microscope. The action of water alone loosened a small percentage of the adherent dirt particles which were seen to exhibit movements of the usual oscillatory character. The covered glass cell in which the fibres were put was specially arranged with very small side tubes, by means of which different liquids could be allowed to flow gently into the cell and bathe the fibres without much disturbing them. When soap solution was substituted for water, and the grease binding some of the groups of particles together began to mix with the solution, the individual particles in the groups of dirt adhering to the fibres were seen to start oscillating through exceedingly small distances, but these increased as more thorough removal of the grease left the particles freer to separate from one another. At this stage the soap solution was gently washed away with distilled water, and groups which still remained fairly intact were watched for an hour and their constituent particles were seen to continue their restricted oscillations. Free particles in the liquid exhibited active movement. A one per cent. solution of common salt was then made to flow gently into the cell. In a short time a large number of free particles had either joined together in groups or had settled on the fibres, and the oscillating movements of the groups were seen to have practically ceased. Water was then washed gently through the cell for some time, and finally the fibres were again irrigated with soap solution. The experiment was watched until in about three hours all the groups had practically broken up into free particles, which, either when near the fibres or in the open fluid spaces, were seen to persist in active oscillations. Similar experiments made with alkaline solutions showed that when these were used at a strength much greater than that necessary to assist soap as an emulsifying agent, and to prevent any formation of acid soaps, they exerted an influence in retarding pedesis, much less certainly than that of common salt and similar substances, but still distinctly perceptible. Apart, therefore, from the reasons given in the former lecture, the use of strong solutions of alkalies is a mistake from this point of view.

The results of a very large number of experiments leave it somewhat doubtful whether any substances promote pedesis, so as to increase the movements of perfectly clean insoluble

particles, beyond what they would exhibit in really pure water, and whether solutions, which are stated to favour pedesis, act in any other way than to neutralise or render inoperative other substances which may be present, and exerting a retarding influence, for example, the retarding action of weak common salt solution can be counteracted to a very great extent by excess of soap. For practical purposes, however, this theoretical aspect of the question need not be considered further. What is clear is that certain conditions must be observed in order to give pedesis full effect, and that the presence of saline substances acts prejudicially. The necessary conditions for the full effect desired involve the use of as little alkali as possible, of water containing no excessive amount of dissolved solids, and of a soap which shows no retarding influence on pedesis, but which on the contrary favours its continuance and activity as much as possible. To assist in ascertaining the effects of various soaps in this connection a number of pure soaps was made, and the relative electrical conductivities of equivalent solutions of them were determined. The conductivity of any true soap solution is very low indeed, but comparative experiments show that the lower it is in any one series of soaps the higher are the molecular weights of the fatty acids from which the soaps are made, and that dealing with ordinary soaps, it is lowest for the alkaline salts of oleic acid; solutions of ammonium oleate being somewhat less conducting even than equivalent solutions of potassium or sodium oleate. Comparative experiments show also that so far as pedesis is concerned the alkaline oleates are the most favourable substances to employ for exhibiting it in its greatest possible activity in a soapy fluid.

Time is an important element to be considered if full advantage is to be taken of these oscillatory movements as assistants in ridding fabrics of dirt. What can be done with soap and alkali and with a high temperature and mechanical agitation can often be equally well accomplished in the cold with less soap and alkali and with much less chance of damage to the fabric if a sufficient length of time can be spared for the operation. Attention is called to this which experience has shown to be a fact, because it often happens that very dirty silk, or woollen articles, or delicate lace would suffer from the manner in which they must necessarily be treated if they are to be washed rapidly, while no damage can occur by simply leaving them to soak for some hours in a solution of one of the alkaline oleates.

This opportunity may be taken for considering briefly the character of a soap to be used with woollen goods. It has often been stated that potash and not soda soaps should be used for wool, and that the former yield better results in every way, the wool being left in its original soft and springy condition. This may very likely be the experience of many launderers, but it is doubtful whether the results if superior are to be considered as due to any special properties of potash soap as such. Careful comparative experiments with potassium, sodium, and ammonium oleates in a practically neutral condition do not show an appreciable difference in the behaviour of the three soaps so far as the final condition of the wool is concerned. It is possible that the advantage believed to be connected with the use of soft soap for flannels, &c., may be due rather to the greater solubility of potash salts of mixed fatty acids, admitting of the use of more soap at a lower temperature, to the small amount of free alkali which used to be present as a rule in the older forms of soft soap, and to the fact that soft soaps were at one time made from oils which contained a high percentage of the glycerine compounds of oleic and analogous acids. It is certainly very doubtful whether some of the soft soaps recently examined, and found to contain much free alkali could, in any hands, yield such good results as a neutral oil or tallow soda soap of high quality. It has been suggested that the glycerine present in soft soaps has some good effect on wool, but it is difficult to see what beneficial action it can have during the washing process. It is sometimes the custom, however, to avoid rinsing out the soap completely from flannels, and it is possible that the small amount of glycerine left in as well may tend to keep the fibres pliable, but the amount is very small, and just as good results can be obtained with copious rinsing, or with neutral soaps free from glycerine. A number of experiments was carried out on the shrinkage of flannel, and the process was watched under the microscope when pieces of the fabric were being heated in water alone, in soap and water, and in various strengths of different alkalies. The details of the experiments need not be considered here as they would occupy too much time to describe, and are moreover of little practical interest compared with the general conclusions to be derived from them. The mechanism of the shrinking or felting of

woollen articles can be understood at once when wool fibres are examined by the microscope and their general structure is seen. The imbricated scales covering the outsides of the fibres project considerably and present many hook-like edges, the catching of which in one another causes the fibres to become so entangled and intertwined as to be practically inseparable. Motion of the fibres is clearly needed to bring about this entanglement, and therefore the expansion, contraction, and twisting which result from rapid alternations of temperature are to be avoided as much as possible.

It was found in a number of trials with different specimens of flannel, &c., that, after the first inevitable shrinking had been completed, exposure for some hours without agitation to the action of water at a temperature of 32° Cent. (90° Fahr.) produced no further appreciable change, but that the same treatment, combined with vibration, caused, as might be expected, a marked shrinkage in a comparatively short time. A similar result, but less extensive, was obtained by rapidly and frequently changing the temperature of the water without, however, exceeding 90° Fahr. When the fabric was kept still, very little curling or twisting of the individual fibres at this temperature was noticed under the microscope, but on heating the water to 50° Cent. (122° Fahr.) movement was distinctly noticeable and some shrinkage occurred.

The addition of alkali (·05 per cent. Na_2CO_3) produced considerably more twisting of the fibres even at the lower temperature of 90° Fahr., with the result that more marked shrinkage took place. This strength of alkali would never be used with woollen articles by any launderer of experience, but the effect is mentioned to emphasize the necessity of avoiding any free alkali other than the very small amount which results from the action of water on a neutral soap.

An average strength of soap solution at 90° Fahr. was not found to have any marked action in promoting the twisting of the fibres, although more was noticed than in the case of water alone, but the shrinkage was negligible.

Without discussing the different kinds of woollen fabrics, and various methods of weaving or treating them in relation to the question of shrinking, the general conclusion appears to be that to retard shrinkage as far as possible, the temperature of the washing fluid should not exceed 90° Fahr., only neutral soaps should be used, and all agitation which can be prevented, whether arising from injudicious mechanical treatment or from rapid alternations of temperature during the washing or in the subsequent drying, should be avoided. There is good reason to add that the precaution of thorough rinsing after washing should always be taken.

It may, however, be mentioned that sometimes a flannel which has been washed with great care for many times without any shrinkage will almost suddenly develope a tendency to shink to a very noticeable extent. It is not easy to say why this occurs, but the probability is that a gradual slight change takes place in the fibre in the course of time and with repeated washing, due to the affinity of wool for alkali which causes it to retain a trace even when the amount of alkali present in the washing fluids used was very small and precautions had been taken to ensure thorough rinsing.

In its chemical reactions wool may be described as both acid and basic, that is to say it shows an affinity for alkalies due to its own acid nature, and also an affinity for acids due to its basic character. When wool which has been thoroughly cleansed and purified is steeped in a weak solution of caustic soda it absorbs alkali from the solution, and this alkali cannot be entirely removed except by prolonged and repeated washing with water to an extent quite impracticable in the ordinary course of laundry work.

The following experiment with fresh Norfolk wool specially purified will illustrate this. Five grams of wool were steeped in 250 cubic centimetres of a ·1 per cent. solution of caustic soda for three days. The wool was then washed repeatedly for several days in distilled water. The quantity of alkali retained by the wool was determined and found to be small, amounting to not more than ·002 grams of caustic soda ($NaOH$) or ·04 per cent. of the weight of the wool. With still more prolonged washing and soaking in distilled water, less alkali still was found to be retained by the wool, but the alkali could not be entirely removed unless the washing water were made feebly acid with, for instance, a little acetic acid. Another experiment, with five grams of wool steeped in the same strength of alkali for the same time, was made, but in this case the wool was well rinsed and squeezed in four changes of distilled water. The amount of alkali retained was found to be ·014 grams of caustic soda, or ·28 per cent. of the weight of the wool. From strong solutions of caustic soda wool will absorb very considerable quanti-

ties of alkali, but very much less in the case of the milder alkalies such as sodium carbonate or borax, and less still from soap solutions. It is, of course, understood that in ordinary washing wool would never be exposed to the action of caustic alkali, as in these experiments, but they serve to show how with repeated washings small amounts of alkali can be accumulated until a change may be brought about in the fibres of a woollen fabric sufficient to give rise to shrinkage. With a view to preventing this possibility, the articles after having been thoroughly rinsed might be soaked in a weak solution of acid containing, for example, not more than 1 per cent. of glacial acetic acid. Fluid preparations stated to preserve the softness of flannel and to give it a fine finish are occasionally offered to launderers. In all the examples which have been examined free sulphuric acid has been found to be the main constituent. The use of any preparations of such a nature is to be condemned, for although wool offers a far greater resistance to acids than it does to alkalies it retains small amounts. In the case of such an acid as sulphuric acid, concentrated as the traces of it would become on drying and heating the fabric, the fibres would inevitably be affected and made rotten in time. Acetic acid is somewhat less readily retained by wool, and its action on the fibres under the conditions described would be very slight indeed.

Before proceeding to the subject which is to occupy the latter part of this lecture, viz., simple methods of identifying and separating the fibres of the ordinary materials which the launderer has to deal with, it may be useful to call attention to an easy way of removing such ingrained stains as sometimes occur on articles which have come in contact with machine grease or some similar form of very finely-divided dirt associated with fatty matter. In the preliminary stages of washing it may, and, in fact, often does, happen that such grease is spread by heat over a larger portion of the fabric, and much of the dirt is left behind in a patch, in a manner analogous to the separation of particles in the experiments on filter papers, which have been described. Had sufficient soap with a little alkali acted on the grease at first, so as to produce a good emulsion, both grease and dirt would have been washed away together; and, therefore, one method of treating the stain would be to rub in fresh grease, and then to attack it with a liberal supply of soap. It is, however, far better to rub oleic acid, which is liquid at the ordinary temperature, well into the stain, and, when it has thoroughly penetrated the fabric, to add a little weak solution of ammonia so as to form a strong solution of an ammonia soap in most intimate contact with the fibres and the dirt. On gently kneading and pressing it will be found that as the soap is forced out it carries the dirt with it, and a wash with water, with perhaps a little more dilute ammonia, will remove all perceptible traces of the stain. In this way it has been found that marks of this nature which have resisted several washings and the use of strong alkalies have been readily removed in less than five minutes.

It is not necessary for the launderer to acquire such a knowledge of the nature and reactions of all the various fibres which may be present in fabrics as would enable him to make complete qualitative and quantitative analyses of them, but it is very useful to him to be familiar with simple tests and methods for the identification and approximate separation of the common textile fibres with which he has to deal in the ordinary course of his work. These include wool, silk, linen and cotton, and less frequently ramie and jute. No attempt will be made to give more than a few reliable tests and methods, or to deal with minor distinctions between fibres such as different wools and various forms of cellulose fibres, for the purpose of determining their original sources.

The microscope affords one of the readiest and most useful means of identifying fibres. An instrument of quite a simple form only is needed, provided its optical part is of good quality. The amount of amplification required is, roughly, about 300 diameters, but it is convenient to be able to use a much lower power of about 50 diameters for a general survey of portions of a fabric. A good ⅓-inch objective (initial power 30 diameters) will bear an eyepiece giving a magnification of 10 diameters, and this combination, which allows of a fair working distance between the object and the lens, will be found convenient for the higher power, while a good 2-inch objective with the same eyepiece will afford the lower magnification. It is a great advantage to have some simple form of condensing lens fitted under the stage for focussing the source of light on the object. Higher powers and better optical appliances generally are needed for exhibiting some of the finer structure of certain fibres, but those mentioned are sufficient for the purpose of identifying fibres and studying their general structure. It would be impossible to explain

adequately the appearance of fibres under the microscope even with the help of a number of illustrations and photographs. It is better to suggest that the launderer who wishes to take advantage of the assistance which the microscope can give him should secure authentic specimens of various fibres and should familiarise himself with their appearance, and also with that of the fibres of fabrics which have been in use for some time, and have gone through the different processes of the laundry. It may be remarked in passing that a microscope is of use to the launderer for purposes other than the identification of fibres, such, for example, as the examination of starches, some kinds of glazes, and many other substances with which he has to deal, and to which foreign matters may be added as adulterants.

Methods of separating the constituents of a fabric, which can be easily applied by the launderer, are based on the following properties of the chief fibres. All forms of wool which are likely to be met with in the course of ordinary work, are completely dissolved if warmed with a solution of caustic soda containing 10 per cent. of NaOH. In such a solution, linen, cotton, and other varieties of cellulose are practically insoluble. A mixture of cotton and wool, therefore, can in this way be separated by destroying the wool and leaving the cotton. Cellulose is freely soluble in the cold in a solution of zinc chloride in strong aqueous hydrochloric acid. This solution may be prepared by dissolving one ounce of solid zinc chloride in two fluid ounces of the strongest solution of hydrochloric acid. By soaking a fabric of mixed wool and cotton fibres in this solution the wool will be left, as it is practically insoluble, although its fibres will be found to be somewhat changed.

Another method for removing cotton from wool, and one used on the large scale, is based on the greater readiness with which cellulose is disorganised by acids and the comparative stability of wool fibres under the same treatment. The mixed fabric is well soaked in a weak solution of hydrochloric acid (about one volume of strong hydrochloric acid to nine volumes of water), and then dried without rinsing. When dry the fabric is held and turned before a fire until it has acquired a dark scorched appearance on both sides. Under this treatment the cotton will have been rendered so friable and dusty that it can be beaten out of the fabric leaving the wool apparently uninjured.

Silk is somewhat less easily affected by alkalies than wool but much more readily by acids. No satisfactory separation of silk from wool can, however, be made by the use of simple alkaline solutions, as these will break up silk and dissolve too much of it if they are strong enough to dissolve wool completely.

The fibres of ordinary silk, *i.e.*, silk from the mulberry silkworm, *Bombyx mori*, as they are generally present in fabrics, are completely soluble in strong hydrochloric acid, and as neither wool nor cotton is dissolved by this reagent, silk may be separated by its use and the presence of the other fibres revealed in mixtures of wool and silk or cotton and silk. No simple or satisfactory method can be given for removing either wool or cotton from their mixtures with silk so as leave the silk intact.

The statement that silk is soluble in strong hydrochloric acid requires some modification. Raw unwashed silk consists mainly of an outer coating of silk glue called sericin, and an inner core of another nitrogenous body, containing less oxygen called fibroin. It is this latter substance which is completely soluble in hydrochloric acid. Sericin swells and gelatinises in this acid, but is not readily soluble in it. As a rule, this silk glue, which is soluble in hot water and soap solutions, or weak alkalies, is removed in the ordinary course of preparing silk for the manufacture of fabrics, but it can be rendered insoluble, and occasionally it has been found present in sufficient quantity to retard solution of the silk in hydrochloric acid, the fibroin dissolving and distorted casts of the silk fibre being left. The same result has been seen with silk which has been coated with gelatine which has been rendered insoluble in hot water or soap solutions, but in both cases the prolonged action of strong hydrochloric acid dissolves the silk, if not completely, to such an extent as to make its removal from wool or cotton quite easy with a little manipulation. There are other silks from different silkworms, of which Tussah silk may be taken as a good example, which show much greater resistance to the solvent action of hydrochloric and other acids, as well as to that of strong alkalies. There are methods known for separating such silk from wool and cotton, but their application need not be considered here, as the object is not to describe processes for the quantitative analysis of fabrics, but to give such methods of separating fibres from one another as will assist in their identification. Those which have been given, supplemented by microscopical examin-

ation and the simple tests which are now to be described, should enable the launderer to recognise the character of any of the more common fibres.

Wool and silk are rapidly dyed yellow by immersion in a solution of picric acid (about ·5 per cent). The cellulose fibres, such as linen, cotton and jute, do not take up the colour. On account of the sulphur contained in wool, a warm, dilute solution of caustic soda (about 1 per cent. NaOH), to which a few drops of a 5 per cent. solution of lead acetate have been added, will colour wool a dark brown, owing to the formation of lead sulphide. Silk and cellulose being free from sulphur do not give this reaction.

The animal fibres, wool and silk, give an intense magenta colour when treated with a solution prepared in the following way. A one per cent. aqueous solution of fuchsine (rosaniline hydrochloride or acetate) is decolourised by adding solution of caustic soda drop by drop, and is then filtered. The fabric is soaked in this solution warmed to about 100° Fahr., for a minute or two and then well rinsed with water. It is next placed in dilute acetic acid, when the colour will be developed. Cotton, linen, and other cellulose fibres remain undyed. The method of preparing the solution given is the usual one, but rather better results in some cases have been obtained by bleaching the rosaniline solution first with sulphurous acid and rendering it alkaline with caustic soda just before making the test. Such a solution is used cold or only slightly warmed.

Jute and other fibres containing lignified cellulose show a marked reaction with phloroglucinol. The test is made by immersing the fibre in a ·5 per cent. solution of phloroglucinol in strong alcohol until it is well saturated with it, and then placing it in strong hydrochloric acid, when a deep red colour will be produced. Another test for jute which is easily applied consists in soaking the fibre in chlorine water (conveniently made by adding hydrochloric or sulphuric acid to a solution of chlorinated lime), and transferring it, after rinsing, to a strong solution of sodium sulphite, when a magenta colour is developed.

No simple and satisfactory colour tests can be given for distinguishing between linen and cotton. There are several which are frequently described and which are more or less applicable to the unbleached fibres, but for linen and cotton or mixed fabrics in the condition in which they reach the launderer, no method of distinguishing them is of any practical value compared with the certain one of the microscopical examination of small portions of the fibres from both warp and weft, gently teased out in a drop of water on a glass slip and covered with a thin cover glass.

Artificial silks, such as may be met with in laundry practice, consist as a rule of fibres obtained by forcing various solutions of cellulose through capillary tubes into liquids capable of setting and coagulating the thin streams of viscid solution. The general appearance under the microscope may resemble that of silk fibres to a considerable extent, but negative reactions with picric acid or fuchsine solutions, comparative insolubility in warm 10 per cent. caustic alkali, and the absence of the marked odour of burning silk on igniting a few threads, will prove that the material is not true silk.*

The colour tests for the various fibres which have been described are clearly not suitable for dyed fabrics unless these are first bleached, nor of course could they be applied to articles in use, but minute portions can generally be obtained, without damage to the material, sufficient for making the tests or an examination by the microscope.

The knowledge of textile fibres which a launderer obtains in his general experience makes it as a rule unnecessary for him to require special tests to recognise the nature of an ordinary fabric, but when any doubt arises of the genuineness of an article and it becomes a question of the treatment which it should receive, or when an accident has happened which might be ascribable to adulteration of a fabric, it is of real value to him to be able to deter-

* The three chief varieties of artificial silks or lustra-celluloses as they are preferably called are those prepared (1) from nitrated celluloses dissolved in some solvent such as a mixture of alcohol and ether, the fibres being subsequently de-nitrated, (2) from solutions of cellulose thio-carbonate, (3) from solutions of cellulose in ammoniacal cupric oxide. The fibres of (1) swell up, become gelatinous and practically dissolve when boiled with 10 per cent. caustic soda or with concentrated hydrochloric acid. The fibres of (3) offer the greatest resistance to these reagents and retain their form even when boiled with them for some considerable time, although in the acid they are broken up into short lengths. The fibres of (2) resist the action of the alkaline solution to nearly the same extent as those of (3), but they are more readily affected by strong hydrochloric acid though not to the same extent as the fibres of (1), being only partly dissolved after long boiling in the acid. Each of the lustra-celluloses shows more tendency than ordinary cellulose to react with the bleached fuchsine solution. The fibres of (3) give the least, and of (1) the most colour which, however, never reaches a depth anything like that obtained with natural silks. None of the lustra-celluloses is dyed by a solution of picric acid even when boiled with it, and this difference between their fibres and those of natural silks forms perhaps the most useful distinction between them.

mine for himself the character and quality of the constituent fibres.

Much that is of interest in connection with these lectures has had to be left out, and much which could well have borne more extended treatment has had to be dealt with somewhat briefly, but perhaps sufficient has been said to indicate the interesting and varied nature of the problems which arise in the apparently simple process of washing.

It is hoped that towards the solution of such problems, these lectures may help to the extent of stimulating those who are engaged in laundry practice to regard their subject as one needing investigations, and their occupation as one affording the best opportunities for making them.

BUCHAREST PETROLEUM CONGRESS.

By Léon Gaster.

The third International Petroleum Congress which was held at Bucharest from the 5th to the 18th of September marks an important event in the history of the development of the petroleum industry, this being the first time that the Congress has been held in a petroliferous country, and also the first occasion on which a Government showed its interest in the movement officially by giving both financial and moral support.

The number of members of the Congress exceeded 700, of whom more than 300 were from various countries scattered all over the world. Different Governments, such as the German, Austrian, French, Italian, American, Hungarian, and Belgian sent official delegates to attend the deliberations of this international gathering, but in the case of England only the London Chamber of Commerce was officially represented.

The official opening was celebrated at the Athenæum Palace on Sunday morning at 10.30. The Minister of Domains, Commerce, Industries, &c., Mr. A. Carp, declared the Congress open, giving in his speech the history of the development of the petroleum industry in Roumania. This speech was followed by another from the Prime Minister, Mr. D. A. Stourdza, who also gave a detailed description of the petroleum industry, indicating at the same time the programme for the future activity of the Government in all the matters relating to the development of this industry.

The work of the Congress was divided into three sections, the first dealing with the geology, exploration, and exploitation of the oil fields; the second dealing with the chemistry and technology of petroleum; and the third dealing with legislation and commerce.

Out of the 300 foreign members of the Congress, over 180 representatives actually came to Roumania, the following countries being represented:—Austria with 48 members, Germany with 41, France with 25, Russia with 15, Holland with 13, Hungary with 9, England and Belgium with 7 each, and with smaller numbers from Italy, United States, Servia, Bulgaria, Sweden and Switzerland. The actual work of the Congress began on Monday morning, September 9th, at the University of Bucharest, where the members discussed the papers read before the various sections of the Congress.

The progress of the production of petroleum during the last five years has been extremely rapid. It is expected that at the end of this year the output in Roumania will exceed 1,000,000 tons. The capital invested in the petroleum industry exceeds (185,000,000 francs) £7,400,000. The contribution of the different countries is apparently made up as follows:—Germany £2,960,000, France £1,240,000, Holland £880,000, Roumania £640,000, Italy £600,000, America £500,000, Belgium £200,000, England £120,000, and several other countries about £260,000. The most important concern at present is the "Societá Anonima Romana," which has also a splendid refinery capable of dealing with 1,500 tons of oil per day. There are several other refineries erected and some are in course of erection, all conducted by well trained chemists. Mention may be madeof the refineries "Vega," "Aurora," "Astra," "Cernavoda," and that of the Roumanian American Company, near Ploesti, &c.

Of the present total production of oil, 92 per cent. is received from the exploitation of private properties, and only about 8 per cent. from the working of the State lands. Ninety per cent. of the total production is derived from the district of Prahova and about 65 per cent. of this is obtained from the fields belonging to the region of Grausor, Mislisoara, Bustenari, and Doftanetz. It is estimated that the mean production per acre in this region reaches about 10,000 tons.

For the transport of petroleum there are several methods available. The suggested pipe line to the Black Sea has not as yet been constructed, but in the district of Prahova there are about 40 pipe lines in existence with a total length exceeding 254 miles, the diameter of the pipes varying between 2 and 5 inches, but in exceptional cases 6 inches. The longest pipe line belongs to the American Roumanian Co., and runs from Moreni to the Gageni railway station. It is about 22·3 miles long, and is 3 inches in diameter. The average price charged for the transport of crude petroleum from Bustenari to Baicoiu railway station, a distance of about 11·7 miles, is £1 4s. per wagon o 10 tons, which works out to a little over ·25d. per ton-mile. There are a veiy great number of tank wagons in use for the transport of petroleum to the storage tanks at Constanza or to some ports on the Danube. The transport rate charged per ton-mile is about ·32d. In the year 1903 only 744 tank wagons were available, most of them being private property.

In the year 1906 over 1,500 tank wagons were in use of which over 1,000 belonged to private owners and only 97 belong to the State railway, but in 25 years hence the remainder of about 400 tank wagons will be passed on to the State.

The export of oil has increased enormously during the last few years, and this year it exceeded 327,000 tons, representing a value of over £1,000,000, of which about 28 per cent. are estimated to have been imported to England. Since the year 1898, when foreign capitalists first became interested in the oil industry, the exploitation of the oil fields has been exceptionally rapid. In comparing the increase of production of petroleum over the whole world between the years 1900 and 1906, one finds that in this period the production of America increased by 193 per cent., of the Dutch Indies by 317 per cent., and Galicia by 233 per cent., and that of Roumania by 355 per cent. In Russia, however, the production has decreased by 13·8 per cent.

The important rôle which the petroleum industry is destined to play in the future may be judged from the fact that the total yearly production all over the world is already estimated to exceed 28,000,000 tons. For the year 1906 the amount obtained from the different countries was as follows:—From the United States 16,000,000 tons, from Russia 8,000,000 tons, from the Dutch Indies 1,350,000 tons, from Roumania 887,000 tons, from Galicia 760,000 tons, from India 560,000 tons, from Japan 175,000 tons, from Germany 80,000 tons, and from other countries about 90,000 tons, making in all about 28,000,000 tons. The import of oil in England alone is now estimated at more than 300,000,000 gallons per annum, and when the new decision to employ liquid fuel for H.M.'s Navy comes into force, the use of oil will be very considerably increased.

The Congress proper lasted for five days from Monday to Friday afternoon, when the official closure took place at the Athenæum Palace in the presence of a large company. After the official closing of the Congress, two important excursions were undertaken, one to visit the works of the port at Constanza on the Black Sea, and the other to the oil regions in Moldavia, which latter was under the guidance of Professor S. Atanasiu. The majority of members inspected the port at Constanza. The work at the port is progressing very rapidly. The export facilities will be considerably increased when the port is completed, even up till now there have already been erected 19 storage tanks with a capacity of 5,000 cubic metres each, and it is intended to further increase their number as circumstances render it desirable. The facilities for pumping are also very great. A tank steamer of 4,000 tons could be charged in less than 24 hours, which is an enormous advance over the best that could previously be done.

The nett result of this Congress may be very great for Roumania, if in the opinion of the eminent experts geologists, who were present at the Congress, the large tracts of land belonging to the State, to private owners and to companies, could be looked upon as worthy of further systematic exploitation. The revenue derived by the State from the direct taxations provided by law, as well as that obtained from the traffic on the railway and other means of transport, may in time become a source of steady and increasing revenue to the country. For the present, the majority of the population are farmers, Roumania being mainly an agricultural country, it will naturally be of very great importance to know on what other natural resources of wealth, the Government can fall back for making reserves, in order to cover the deficits which, as a rule, follow years of bad harvest. As a national asset the petroliferous lands belonging to the State, may eventually be used to cover part of the enormous national debt.

The number of people employed in the petroleum industry at present is only a little over 8,000. It may be pointed out that great improvements have been made in the legislation dealing with the granting of concessions, such as to safeguard the interests of the investors, by making the title-deeds more secure than was formerly the case. There are, however, further improvements necessary in this direction, and I am given to understand that suitable amendments are now under the Government's consideration.

Roumania has done a great deal towards encouraging the development of home industries, inducing the population to realise the great industrial development of which the country is capable, and not to restrict themselves only to farming, which at present forms their chief occupation.

At one of the banquets given at Constanza, the Prime Minister, Mr. D. A. Stourdza, in his toast described shortly the history of the European Commission of the Danube, and full credit was given to the English engineer, Mr. (now Sir C.) Hartley for his most valuable share of work, first as chief engineer and afterwards as Consulting Engineer to the Commission.

After a sojourn of two days at Constanza, the majority of the delegates paid a visit to Constantinople, the Roumanian Government placing a special vessel at their disposal. Thus ended the programme of this most interesting and instructive international gathering.

At the closing meeting, it was decided that the next Congress shall take place at Lemberg, in Galicia, in the year 1910.

RUSSIAN PEASANTS AND THE LAND.

In his 1905 report (Annual Series, No. 3653, page 28), Mr. Consul Smith, commenting upon the condition of the peasantry in the Odessa consular district, maintained "that it was not the want of land which kept the peasantry from making both ends meet," but the antiquated "three field system" of cropping, whereby one-third of the area lies fallow. Since then several practical agriculturists have gone into the

subject, and their conclusions support the Consul's contention. One expert, with some show of reason, maintains that were the Russian peasantry to take a lesson from their German neighbours, they would be able to increase the "growing" area of their present holdings by something like 30 per cent., equivalent to an increase of 49,500,000 acres, or, in other words, that the peasantry with their present system of farming allow to lie fallow an area equal in extent to what they now demand should be allotted to them. It is further maintained that if the yield from the peasant-held land was even brought up to the present average of the large landowners, who in turn cannot show the same yield as owners in Western Europe, they could thereby produce something like 4,838,710 tons of grain for export—a return which would pay all taxes, payments for land purchase, and leave a comfortable margin over. The statistics of average yield from landowners and peasants in sixteen districts show the landowners' harvest as being 53½ per cent. more than that of the peasant, which goes to prove the foregoing assertion. This question of the cultivation of land is not one which only affects the welfare of the peasantry; the future of Russia as an exporting country is also involved. If the peasantry obtain possession of the land, and cannot produce the quantity or the quality of grain at present produced by the large landowners, the results in the export returns of the country under the head of "Food Products" must be disastrous.

Much is said about the drink bill of the United Kingdom, but the consumption of spirits in some parts of Russia is greatly in excess of anything known outside Russia. Official statistics show that Kieff stands third in the quantity of spirits consumed, but the consumption is enormous having regard to the population. The consumption of vodka in 1905 was 7,340,258 gallons of 40 degree, and as the average price at which this strength of spirit is sold by the trade is 6s. 1d. per gallon, it will be seen that the sum of £2,232,660 was spent upon this spirit alone. Taking the population of the province as being 4,200,000, the figures given by Mr. Consul Smith, there is thus 10s. 8d. per head spent on spirits. In comparing this with the quantity consumed per head in the other countries of Europe it is necessary to keep in view not only the sum spent, but also the quantity consumed per head, viz., 1·75 gallons, as well as the exceedingly low average wages earned by the working people of the province, with a peasant class representing 80 per cent. of the total. Landowners bitterly complain of the ruin caused to the peasantry by the excessive drinking in the villages. Mr. Consul Smith gives instances where the wages earned by the villagers for the work done during the year on the estates has exactly tallied with the year's turnover in the State spirit store in the village. In one instance, a large farmer paid his workpeople £750 in wages on the eve of a big holiday, and £690 of this hard-earned money was spent in vodka before the holiday treat came to an end. It is a striking fact that in the famine-stricken districts there has been an increase of £1,789,474 in the consumption of state spirits, nor is this anything uncommon in connection with Russian famines. How is it, asks the Consul, that starving peasants, without money to buy bread or corn, can obtain money to buy drink, not to mention an increase in quantity?

THE SMYRNA WINE INDUSTRY.

The climatic conditions of Western Asia Minor are exceptionally good for producing wine. When it was discovered that wine produced in that district could readily be exported to such great wine-growing countries as France, Italy and Germany, an impetus was given to the industry throughout the vilayet or province. With the advent of improved methods of culture, and a rational study of the varieties of wine which thrive best in the soil, Smyrna has been able to build up a growing and prosperous trade with foreign countries. According to the American Consul at Smyrna, the culture of the wine-grape has also spread from Smyrna to the interior of the vilayet. In contradistinction to the vineyards of Smyrna, which are principally arranged upon slopes, those in the interior have been laid out on the flat plan. The products of the vineyards of Turboli and Aiden have become celebrated for their rich flavour and splendid aroma. During the past few years, German wine-dealers have been interesting themselves in Smyrna wine, and several large vineyards are now under German management. This is having a wholesome effect for the reason that scientific methods are being introduced, and Greek vineyard owners, who have thus far practically controlled the market, are losing no time in taking the necessary steps to bring their vines up to an equal state of production. The wine produced on the mainland will soon be in a position, it is said, to compete favourably with that of Samos and other islands of the archipelago. One thing, however, which militates against a rapid development of the foreign trade is the high export duty. The wine exported from Smyrna finds its way chiefly to Hungary, where it is mixed with the native wines of that country, and then sold in European markets under the well-known name of Tokay. The grapes of Smyrna are not only made into wine, but they also produce raisins, which are extensively exported to European and American markets. The proeess of drying takes places in the open field. The ripe grapes are passed through a thin solution of alkali in order to prevent them from becoming mouldy, and also to remove certain small insects which prey upon the fruit from the time of the bud until it is picked. They are cured in the hot sun, and are finally sent in large baskets by camel transport to the nearest railway station, and thence to the port of shipment. Generally speaking, the process of pressing grapes in Asia Minor is very primitive. Apart from Smyrna, where a number of up-to-date wine presses have been introduced, the usual methop

of pressing the juice from the grape is by blocks of wood, marble, or stone, and even the feet. A large quantity of alcohol is imported into Turkey every year, chiefly from Russia and Italy, for the purpose of strengthening native wines. From the stalks and pips of the grapes a spirit is distilled which forms the favourite drink of the population. It is used either plain or flavoured with gum of the mastic tree. This spirit is mixed with water, and is said to make a pleasant and refreshing drink.

THE PIMENTO INDUSTRY IN JAMAICA.

Pimento, a dark-coloured berry, is the size of a pea with the remains of the calyx attached, and possesses the odour and flavour resembling a mixture of cinnamon, cloves and nutmegs, from which fact it derives the name of allspice. While an inferior quality grows in Mexico and parts of Central and South America, Jamaica is the country from which pimento is exported. The tree is a handsome one, attaining a height of thirty feet, with a light ashen or brown-coloured bark, which peels off in flakes as the trunk increases in size. It grows wild, and plantations or pimento walks are established by allowing a piece of land near pimento trees to become overgrown with bush, in which the birds deposit seeds from the pimento berries eaten by them, and from these seedlings grow. When the plants reach a certain size, the bush is cleared and the pimento trees are allowed to grow up. To ensure the best results, the trees should not be permitted to grow closer than twenty feet from each other. They will grow on a poor soil, provided it is friable and well-drained, as is the case on the mountain slopes of Jamaica. The tree, according to the American Consul at Kingston, yields a crop when it is seven years old, and the crops increase each year until the tree attains its full size. The berries are gathered while green, after the blossom falls. The usual method pursued is for a person to climb the tree and break off the young branches and throw them down to the women and children, who pick the berries from the stalks, separating the green berries from the ripe ones, and then carry them to the drying places. The berries are dried on trays exposed to the sun, in the same manner as coffee, the process lasting from three to twelve days. Fruit evaporators are sometimes used for drying the berry in wet weather. When sufficiently dry the seeds rattle when shaken and are of a dark colour. A third of the weight of the berries is lost in the drying. They are packed in bags or casks for shipment. In favourable seasons as much as a hundredweight of dried spice has been obtained from a single tree. Ripe pimento berries are used to make pimento dram, a native drink. Stems from the tree are fashioned into walking-sticks and umbrella handles. From the leaves of the pimento an essential oil is distilled. The exports of pimento from Jamaica in the year ended 31st March, 1906, amounted to 91,736 cwts., and in the year ended 31st March, 1907, to 85,294 cwts.

HOME INDUSTRIES.

Open-Hearth Rails.—Discussion has been quickened as to the comparative merits of the open-hearth and Bessemer rails by the rumour that a great railway company has placed an order for 2,000 tons of open-hearth steel rails for the purpose of testing them. Expert opinion is not wanting in support of the contention that the experiment, if made, will prove the superiority of the open-hearth rail over the Bessemer acid rail, and that the days of the Bessemer branch of the iron and steel trade are numbered. Should this forecast prove to be correct it is further contended that the west coast makers would suffer very seriously owing to inability to make open-hearth rails. This is, however, by no means generally admitted by authorities in the west coast steel trade. Many of them maintain not only that the Bessemer acid rail, because of its intrinsic merits, will continue to find buyers, but that the Barrow works, which are the largest rail rolling mills on the coast could, if offered the price, begin the manufacture of open-hearth rails forthwith. The thorough trial of a rail would cover years, and in that time west coast makers now without suitable plant for the open-hearth process would be able to get it, and so be in a position to execute orders.

Paper Yarn.—According to an American official report paper yarn is beginning to be largely manufactured in Germany and the United States. In the latter country it is proposed to start several mills, and in Saxony several are already at work. The yarn consists of cellulose made into flat strips of varying thickness and width. These are spun on specially constructed machines alone, or with the addition of a fine cotton thread. In Saxony the labour cost of producing one kilo (2·2 lbs.) of paper yarn is about a third of a penny, and the wholesale selling price about five pence a pound. Two German mills are turning out 20 tons of paper yarn a day. A manufacturer of carpets is said to have placed an order for 600 tons of the yarn, and one of the largest jute spinning firms on the Continent is said to have contracted for the sole right to make sacking of paper and jute yarns in combination. Amongst other things tapestries, druggets, towellings, laces, and underclothing have been made from the new yarn. It is claimed for it that it does not ignite quickly, and that it is strong and flexible.

Wolfram in Cornwall.—Reference was made in these Notes recently (*Journal*, October 4) to the presence of wolfram in Cornwall where, however, it was said "the ore deposits of wolfram, as a rule, are small and irregular." A correspondent referring to this remark, says that it is not only that the deposits in Cornwall are "small and irregular," their value is much depreciated by the admixture of tin. In Colorado the wolfram is without this mixture, and consequently is much more valuable. A recent in-

vention, the magnetic separator, is only partially successful in separating the ores. The complete separation might mean much to Cornwall, says the correspondent, for there are immense quantities of ore containing wolfram to be found in the dump heaps. It is only in recent years that the value of wolfram has been appreciated.

Bad Spinning Tests.—The latest proposal of the operatives to settle the bad-spinning dispute does not seem to commend itself to employers. It was suggested that a test be made by "ascertaining how many ends break in ten stretches on one mule, and if the average breakage reaches 1·2 per 100 spindles in ten stretches then the spinning shall be considered unsatisfactory." This, employers contend, would not give satisfaction to either side. It would be purely experimental. Who is to say, when and under what conditions the test shall be made? Bad spinning, say the employers, is sometimes caused as much by the operations of the minder as by causes over which he may have no control. It is quite probable too, as is pointed out by the *Manchester Guardian*, that a test made at one time of the day would yield altogether different results from one made at another time. Changes in the atmosphere would have a similar effect, and tests applied at different stages of the building of the cop would bring about dissimilar conclusions. The likelihood is that the proposal would have to be accompanied by so many clauses to determine the conditions under which the experiment should be made that it would end in greater dissatisfaction than now exists.

The Cotton Conference.—The following resolution has been passed at the Cotton Conference that has been sitting in Atalanta:—"That cotton be packed in a bale similar to the Egyptian bale, having a covering of osnaburgs or burlaps; the minimum weight of the bale to be 500 lbs., the maximum weight 750 lbs., and the bale to be marked at both ends, showing grade, staple, and weight; that the ginners inspect the cotton before it is baled, marking the grade on the bale; and that samples accompany the bale to obviate the necessity of opening it until it is actually delivered to the spinners." Representatives of the farmers' associations who attended the Conference declared that the farmers were willing to stamp the name and address of the producer and ginner on the bale in order that the purchaser may readily trace them in the event of complaint as to the cotton. The Conference also recommended that cotton be held for thirty days before ginning in order that much of the moisture now complained of may evaporate, and greater that uniformity as to the length of staple be secured when packing. These would seem to be excellent recommendations and decisions, which, if carried out, would go far to meet the complaints of the Lancashire spinners, but it remains to be seen whether immediate, or early, effect will be given to them. It is pointed out that only a few of the ginners may be able to afford the cost of putting in presses capable of producing the style of bale that has been recommended, and they seem reluctant to "scrap" the compressors now in use. Then, too, many of the compressors belong to the railway companies, and they may place difficulties in the way of handling cotton that has not been compressed by them. Nor are they likely to show any great alacrity in putting in new compressors.

Ground Rents in the Strand.—Some figures given by the *Statist* go some way towards explaining the delay in dealing with the stretch of ground between Wellington-street and the Law Courts. Among the few new buildings upon this area the Gaiety Restaurant and Hotel is prominent. It is now in the hands of trustees for the debenture holders, and it was recently put up for sale by their order. The building extends over an area of more than 10,000 feet, the area of its upper floors being still larger as they project to the extent of about 2,000 feet over the ground floor of the neighbouring premises. The land is held from the London County Council under an agreement for lease for a term of 50 years only from 1905, and the ground-rent payable to the Council is nearly £6,000 per annum, whilst that payable to the owner of the adjoining premises, over whose building the restaurant extends, rises to £900 per annum. This makes the ground-rent paid for the principal portion approximate to 12s. a foot, and that payable to the adjoining owner for liberty to build over his ground nearly 9s. a foot. It is said that the outlay upon the property has amounted to fully £170,000, and obviously it is an investment that would appeal to few. The highest nominal bid at the auction was £100,000, and the property was withdrawn.

Wool Production.—A very interesting and instructive report on the production of wool in Great Britain has just been issued by the Board of Agriculture. It deals with the years 1905 and 1906 and is the first of its kind. In his introductory statement Mr. R. H. Rew says that the inquiry was rendered desirable by "the renewed importance which the recovery in prices in recent years has given to the supply of British wool," and the report shows the lack that has been felt of official information on the subject. The Board has been assisted in the preparation of the report by its agricultural correspondents and market reporters as well as by many flock masters and wool buyers. In order that the possibility of error should be reduced to a minimum it was decided to defer the publication of the results of the first return until the inquiry could be repeated in 1906, and the estimates set forth represent the average returns of the two years. The following is an approximate estimate of the total annual production of wool in the United Kingdom:—Sheep shorn 87,838,000 lbs.; sheep slaughtered 30,250,000 lbs.;

ambs shorn 2,000,000; lambs slaughtered 1,000,000. Total for Great Britain, 121,085,000; total for Ireland, 12,000,000; total for United Kingdom, 133,085,000. But this total, large as it is, represents only 27 per cent. of the gross consumption. The average annual imports of wool (sheep, lambs, and alpaca) retained for home consumption in the two years 1905-6 was 360,000,000 lbs. The bulk of the imports came from within the empire. In the triennial period 1904-6, 81 per cent. came from the colonies, but in 1880-2 the percentage was even higher being, 87 per cent., the growth in the foreign import, such as it is, being almost entirely due to the development of the pastoral pursuit in South America. The report also gives much information as to the wool yield in the different counties, and of the various breeds and crosses. As a rule each breed shows to the best advantage in the district with which it is specially identified. Thus in its native county the Lincoln breed averages 10¼ lb. per fleece for ewes, and 13 lb. for other sheep, as against 9½ lb. and 10½ lb. in Derbyshire, and 10 lb. and 12½ lb. in Nottinghamshire, although in the North Riding of Yorkshire the corresponding averages were 11 lb. and 14 lb. The South Devon seems to be the most prolific wool-bearing variety, the Lincoln and Dartmoor being equal second, while the Devon long-wool comes next. The Oxford Down is first among the short-wooled breeds, the Shropshire second, and the Hampshire third. The report deals, too, with wool production from the buyers' point of view, and sheep farmers will find it worth attention.

Bank Amalgamation. — The Manchester and Liverpool District Banking Company, Limited, and the Lancashire Banking Company, Limited, have entered into a provisional agreement for the amalgamation of the two banks by the transfer of the business and assets of the Lancaster Bank to the Manchester concern. The terms provide that five shares in the Lancaster Bank will be exchanged for three shares in the District Bank, plus the sum of 21s. in cash for each share in the Lancaster Bank. Thus the paid-up capital of the Lancaster Bank of £302,500 will be replaced by £396,000 of paid-up capital in the District Bank, and the cash payment of £57,750. The reserve fund of £300,000 of the Lancaster Bank will be reduced by this additional paid-up capital, and the above mentioned cash payment to £146,250, whilst the paid-up capital of the District Bank will be raised to £1,896,000, and the reserve fund to £1,816,250. Of late the tendency has been for local or county banks to be swallowed up by great metropolitan institutions, and the change will be welcomed by many. The District Banking Company, Limited, will now have no fewer than 175 branches and sub-branches in Lancashire, Cheshire, Staffordshire, Shropshire, Yorkshire, and Derbyshire, and its total resources, amounting to £25,122,000, will give it a leading position among the great banks of the country.

CORRESPONDENCE.

HEATING OF COTTON CAKE, AND ITS PREVENTION.

The attention of the directors of The Cotton Seed Co., Ltd., has been drawn to a reprint in the *Journal of the Society of Arts* (issue of the 11th inst.) of an article extracted from the *Indian Trade Journal*, on the "Heating of Cotton Cake, and its Prevention."

In that article, the writer states that cotton cake—that is, undecorticated cotton cake—made from Indian seed is liable to heat under certain conditions, that consequently, as large stocks of the article cannot be kept, the use of Indian seed for cake is restricted.

It is desirable, however, he says, to prevent heating, and as heating is due to fermentation or bacterial action in the husk (which is commonly called in the trade, the hull) the remedy is to decorticate the seed.

He proceeds to say that no plant for the decortication of Indian cotton seed exists in the United Kingdom, and then propounds a "general idea" of a process for decortication in the hope that persons interested in seed-crushing appliances may be induced to test its practicability.

It is no doubt true that undecorticated cotton cake is liable to heat, but my directors understand that the heating is due, not to bacterial fermentation, as suggested by the writer of the article, but to that liability to combustion which is characteristic of cotton fibre when saturated with oil. Indian cotton seed is covered with a closely adherent matted fibre which cannot be separated in the ordinary process of cake-making, and is left on the hull, forming with the hull and kernel component part of the cake. The liability to heating is not the only disadvantage attendant on the storage and use of such feeding material, and for many years attention was given to the discovery of a method of separating the fibre from the hull, and hull from the kernel, with successful results, some five or six years ago. This method has been for some time in full commercial operation by this company, which holds the patent rights in the process. The decorticated cake made in this company's mill is at least equal to the best decorticated American cake, as will be evident from the fact that it commands an even better price in the market than American cake.

Its keeping qualities have been proved by the application of severe tests, bags of the cake having been sent out by us from London to Bombay, stored in India, and returned to London in perfect condition at the worst season of the year.

The writer of the article does not seem to have made himself acquainted with recent developments in this matter, and we hope you will do us the courtesy of giving as much prominence to this rectification of facts as you did to the article. When we mention that this company is now concerned with proposals for the establishment of mills in India worked by plant similar to that which is being successfully

operated here, my directors are sure that you will recognise that they have a right to expect a prompt contradiction of the statement of facts given by the insufficiently informed writer of the article in the Indian official paper.

My directors desire, in conclusion, to express their surprise that that paper should not have been better informed, seeing that the facts regarding the patent processes of this company were supplied to the India Office some three or four years ago, in connection with a discussion on this same subject, and that we possess Indian patents as well as patents for the United Kingdom.

S. C. ROBERTSON, Secretary.

The Cotton Seed Co., Ltd.,
Oil and Cake Mills,
Cubitt Town Wharf, Poplar, London, E.C.
21st October, 1907.

OBITUARY.

THOMAS FORSTER BROWN, M.INST.C.E., F.G.S.—Mr. Forster Brown, of Springfoot, Stoke Bishop, Bristol, died on the 23rd October at Richmond, Yorkshire, in the 73rd year of his age. For forty years he was deputy gaveller (mineral agent) for the Crown in the Forest of Dean, and as a civil and mining engineer took a prominent part in the development of South Wales. He was one of the joint engineers in the construction of the Barry Dock and Railways, and also of the Vale of Glamorgan Railway. Besides being a member of many societies, he was a past President of the South Wales Institute of Engineers. He was elected a member of the Society of Arts in 1896, and in April, 1899, he read an important paper on the subject upon which he was a recognised authority, entitled "Our Coal Supplies."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Nov. 4...Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Prof. Penberthy, "Some Diseases of Farm Animals."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, in the Theatre of the United Service Institution, Whitehall, S.W., 7½ p.m. Mr. Horatio C. Huggins, "Bridle Roads in the West Indies."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Messrs. Cyril Bergtheil and R. V. Briggs, "The Determination of Indigotin in Indigo yielding Plants." 2. Messrs. R. Gaunt, F. Thomas and W. P. Bloxam, "Analysis of Indigo (Part III.) and of the Dried Leaves of *Indigofera Arcuata* and *Indigofera Sumatrana.*"

London Institution, Finsbury-circus, E.C., 5 p.m. Prof. W. M. Flinders Petrie, "Ancient Egyptian Houses."

TUESDAY, Nov. 5...Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Inaugural address by the President, Sir William Matthews. 2. Reception by the President.

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. Thomas K. Grant, "Practical Demonstration of Autochrome Plates."

WEDNESDAY, Nov. 6...United Service Institution, Whitehall, S.W., 3 p.m. Mr. A. R. Colquhoun, "The Strategical and Economical Effect of the Opening of the Panama Canal."

THURSDAY, Nov. 7...Linnean, Burlington-house. W., 8 p.m. 1. The Rev. George Henslow, "The Origin of the Di-trimerous whorls among Flowers of Dicotyledons." 2. Mr. Albert D. Michael, "Unrecorded Acari from New Zealand." 3. Mr. R. Shelford "*Ænigmatistes africanus*, a new genus and species of Diptera."

Chemical, Burlington-house, W., 8½ p.m. 1. Mr. H. B. Baker and Miss M. Baker, "Gaseous Nitrogen Trioxide." 2. Messrs. H. B. Baker and A. H. Bennett, "The Atomic Weight of Tellurium." 3. Mr. H. M. Godby, "The Isomerism of the Double Sulphites of Sodium and Potassium." 4. Messrs. M. O. Forster and T. Jackson, "Studies in the Camphane Series. Part xxiv. Camphoryldithiocarbamic Acid and Camphorylthiocarbimide." Mr. R. T. Lattey, "The Vapour Pressures of Triethylamine, of Sym-trimethylpyridine, and their Mixtures with Water." 6. Mr. R. T. Lattey, "Liquid Triethylamine." 7. Mr. F. S. Sinnatt, "The Action of Sulphuretted Hydrogen on Solutions of Sodium Hydrosulphite." 8. Messrs. W. J. Pope and C. S. Gibson, "The Alkyl Compounds of Gold. Diethylauric Bromide. Preliminary Note." 9. Messrs. F. B. Power and F. Tutin, "Note on the Constitution of Homoeriodictyol." 10. Mr. F. Tutin, "The Interaction of Methylene Chloride and the Sodium Derivatives of Ethyl Malonate." 11. Messrs. P. C. Ray and P. Neogi, "Preparation of Aliphatic Nitro-Compounds by the Interaction of the Alkyl Iodides and Mercurous Nitrite." 12. Messrs. J. E. Marsh and R. de J. F. Struthers, "Some Mercury Derivatives of Camphor." 13. Mr. G. G. Henderson, "Contribution to the Chemistry of the Terpenes. II. The Oxidation of Limonene with Chromylchloride." 14. Messrs. A. Senier and A. Compton, "The Synthesis of Acridines and Phenonapthacridines; Tetra- and Hexa-methylacridines; Dimethylphenonapthacridines; Dixylylmethylenediamines."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. Orton Bradley, "American Composers."

United Service Institute, Whitehall, S.W., 3 p.m. Colonel C. Delmé-Radcliffe, "The Swiss Military System."

*** CORRECTION.—In Professor Gregory's third lecture on Gold Mining (*ante* p. 1041, col. 1, *note*), *for* "not more than ·002 inch" *read* "not more than ·0002 inch."

Journal of the Society of Arts.

No. 2,868. VOL. LV.

FRIDAY, NOVEMBER 8, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

ARRANGEMENTS FOR THE SESSION.

The Opening Meeting of the One-hundred-and-Fifty-Fourth Session will be held on Wednesday Evening, the 20th of November, when an Address will be delivered by Sir STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., Vice-President and Chairman of the Council. The Chair will be taken at 8 o'clock. The subject of the Address will be "Lord Clive, and his work in the foundation of the Indian Empire."

Previous to Christmas there will be five Ordinary Meetings, one meeting of the Indian Section, and one of the Applied Art Section.

The following arrangements have been made:—

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

NOVEMBER 27.—"The Franco-British Exhibition, 1908." By THE HON SIR JOHN A. COCKBURN, K.C.M.G.

DECEMBER 4.—"Old Age Pensions." By SIR EDWARD W. BRABROOK, C.B.

DECEMBER 11.—"Radio-active Phenomena." (Aldred Lecture.) By SIR WILLIAM RAMSAY, K.C.B., F.R.S. SIR STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., Chairman of the Council, will preside.

DECEMBER 18.—"The Rôle of France in West Africa." By MONSIEUR LUCIEN HUBERT, Député des Ardennes.

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock:—

DECEMBER 12.—"Big Game in India." By REGINALD GILBERT, F.Z.S., late of Bombay.

APPLIED ART SECTION.

Tuesday evening, at 8 o'clock:—

DECEMBER 17.—"How to Make the Most of a Museum." By LEWIS FOREMAN DAY, F.S.A. SIR ASTON WEBB, R.A., F.R.I.B.A., will preside.

SHAW LECTURES ON INDUSTRIAL HYGIENE.

Friday evenings, at 8 o'clock:—

NOVEMBER 29.—The Hygiene of Work in Compressed Air (Diving, Caisson Work, Sub-aqueous Tunnelling, &c.). By JOHN SCOTT HALDANE, M.A., M.D., M.R.C.P. (Edin.), F.R.S. HERBERT LOUIS SAMUEL, M.P., Under-Secretary of State for the Home Department, will preside.

DECEMBER 13.—"Industrial Poisons—Lead and Phosphorus, with special reference to Lucifer Match Making." By PROFESSOR THOMAS OLIVER, M.D.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

CONRAD BECK, F.R.M.S., "The Theory of the Microscope." Four Lectures.

November 25, December 2, 9, 16.

Meetings after Christmas:—

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock (dates not fixed):—

"Screen-Plate Processes of Colour Photography." By C. E. KENNETH MEES, D.Sc., F.C.S.

"The Problem of Road Construction, with a View to Present and Future Requirements." By H. S. HELE-SHAW, LL.D., F.R.S., and DOUGLAS MACKENZIE.

"Recent Improvements in Decorators' Materials." By A. S. JENNINGS.

"The Underground Water Supplies of the Thames Basin." By CLAYTON BEADLE.

"Industrial Entomology: the Economic Importance of a Study of Insect Life." By F. MARTIN DUNCAN.

"Modern Dairy Practice." By LOUDON M. DOUGLAS.

"War Balloons." By AUGUSTE E. GAUDRON.

"The Making of Sound Waves, and their subsequent Reproduction of Sound as Exemplified by the Gramophone." By MARK BARR.

"Siam and its People." By HARRY HILLMAN.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

January 16, February 13, March 12, April 30, May 21.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock :—

January 28, February 25, March 24, April 7.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock :—

January 21, February 18, March 31, April 28, May 26.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

HENRY HARDINGE CUNYNGHAME, C.B., "The Theory and Practice of Clock Making." Six Lectures.

January 20, 27, February 3, 10, 17, 24.

PROFESSOR VIVIAN B. LEWIS, "Fuel and its Future." Four Lectures.

March 9, 16, 23, 30.

WILLIAM BURTON, F.C.S., "The Nature and Structure of the Porcelains." Three Lectures.

May 4, 11, 18.

SHAW LECTURES ON INDUSTRIAL HYGIENE.

Dates not fixed :—

"The Removal of Dust and Fumes in Factories." By JOHN SCOTT HALDANE, M.A., M.D., M.R.C.P. (Edin.), F.R.S.

"The Dangers of Coal Dust and their Prevention." By W. E. GARFORTH, President of the Colliery Proprietors' Association of Great Britain.

"The Hygiene of the Pottery Trade." By WILLIAM BURTON, F.C.S., Chairman of the Joint Committee of Pottery Manufacturers of Great Britain.

"Child Workers and Wage Earners." By MISS NETTIE ADLER, Hon. Secretary to the Committee on Wage Earning Children.

HOWARD LECTURES.

Thursday evenings, at 8 o'clock :—

H. S. HELE-SHAW, LL.D., F.R.S., "The Navigation of the Air." Three Lectures.

March 19, 26, April 2.

JUVENILE LECTURES.

Two Lectures suitable for a Juvenile audience will be delivered on Wednesday afternoons, January 1 and 8, 1908, at 5 o'clock.

INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section was held on Wednesday afternoon, 6th November. Present: Sir Steuart Colvin Bayley, K.C.S.I., C.I.E., Chairman of the Council, in the chair, Sir M. M. Bhownaggree, K.C.I.E., Sir George Birdwood, K.C.I.E., C.S.I., Major-General Sir Owen Tudor Burne, G.C.I.E., K.C.S.I., Henry Luttman-Johnson, John David Rees, C.I.E., M.P., Sir James Thomson, K.C.S.I., Thomas D. Thornton, C.S.I., Lieut.-Colonel Sir Curzon Wyllie, K.C.I.E., C.V.O., with S. Digby, C.I.E. (Secretary of the Section).

PROCEEDINGS OF THE SOCIETY.

INTERNATIONAL EXHIBITIONS.

The following is a first attempt to provide a list, as complete as possible, of Exhibitions held since the first Great International Exhibition of 1851, down to the present date. It is hoped that its publication may attract corrections and additions, so that at some future time it may be possible to reprint it in a revised and amended form. It has been formed from various sources, and one result of this is that the titles show a sad lack of uniformity. In many cases it has been possible to give the proper official title, or a sufficient abridgment of it. In others the available information only suffices to provide an indication of the nature and character of the Exhibition.

The list is intended to include, besides the genuine International Exhibitions, all industrial or technical Exhibitions of an important character. It is to be feared that many of the entries might well be omitted, and it may be taken as certain that the omissions are numerous. Exhibitions of works of art are not included, though even here the rule is not absolute, for it has been thought well to include such an entry as that of the Manchester Art Treasures Exhibition of 1857.

Any suggestions for amendment will be gratefully received.—H.T.W.

1851. LONDON — Great International Exhibition.
1852. CORK—National Exhibition.
1853. BRUSSELS—Industrial Art Exhibition.
,, DUBLIN—Irish Industrial Exhibition.
,, NEW BRUNSWICK—Native Industry Exhibition.
,, NEW YORK—Industrial Exhibition.
1854. CHRISTIANIA—Exhibition of Norwegian Art and Manufactures.
,, FLORENCE—Exhibition of Natural and Industrial Products of Tuscany.
,, LONDON — Educational Exhibition in St. Martin's Hall.
,, MADRID—Industrial Arts Exhibition.
,, MELBOURNE — International Exhibition.
,, MUNICH — Allgemeine deutsche industrie Ausstellung.
1855. MADRAS—Exhibition of Arts, Manufactures, and Raw Materials of the Presidency.
PARIS—Exposition Universelle.
1856. BRUSSELS—Belgian Arts Exhibition.
EDINBURGH—First Exhibition of the Art Manufacture Association.
1857. BERN—Exhibition of Swiss Arts and Manufactures.

PATENTS AND DESIGNS.—THE NEW ACT.

By J. A. LAW, C.P.A.

The Royal Assent has recently been given to an Act embodying alterations in the law relating to patents and designs of great importance to inventors, manufacturers, and others. The Act contains nearly a hundred sections and all that can be done in this article, therefore, is to deal somewhat shortly with the more important innovations.

Except where otherwise expressly provided, the Act is to come into operation on January 1st next, and to extend to all patents granted and designs registered before then, and also to applications then pending.

The Act is divided into three parts, namely:—I. Patents; II. Designs; and III. General. These parts will be treated *seriatim*.

PART I.—PATENTS.

Compulsory Working.—If a patented article or process be manufactured, or carried on exclusively, or mainly outside the United Kingdom, then, unless the patentee prove that the patented article or process is manufactured or carried on to an adequate extent in the United Kingdom, or give satisfactory reasons why it is not so manufactured or carried on, the Comptroller may make an order revoking the patent forthwith, or he may make an order revoking it after a specified interval if the patented article or process be not in the meantime adequately manufactured or carried on within the United Kingdom; but in the latter case, if the patentee give satisfactory reasons for the failure so to manufacture or carry on within the prescribed time, the Comptroller may extend the period by not more than one year. To obtain such an order, application must be made to the Comptroller at least four years from the date of the patent, and one year from the passing of the Act; moreover, any decision of the Comptroller is to be subject to an appeal to the High Court, and no order is to be made that will be at variance with any treaty, convention, arrangement, or engagement with any foreign country or British Possession.

This provision, which, according to Mr. Lloyd-George, is the pith of the Act, introduces a very important alteration into the law relating to patents. It is true that under the previous law it was possible that a patent might be revoked on a somewhat similar ground, namely, that the reasonable requirements of the public with respect to the patented invention had not been satisfied; but this was only as an alternative to the grant of a compulsory license, and no patent has, at any rate in modern times, been revoked on such a ground. Whether the policy of revoking patents for lack of working in this country is sound or not, is at any rate very debatable, and the writer has previously advocated the placing in the hands of the Comptroller, in lieu of the power to revoke, the power to grant to suitable applicants licenses to work patents that have not been worked in this country for a given time after their grant.

Compulsory Licenses or Revocation on Petition to Board of Trade.—Petitions to the Board of Trade for the grant of compulsory licenses, or, in the alternative, the revocation of patents, on the ground that the reasonable requirements of the public with respect to the patented inventions have not been satisfied, are to be referred by the Board of Trade to the High Court of Justice instead of to the Judicial Committee of the Privy Council; the alteration is, of course, made with a view to cheapening the procedure, which, under the old law, has been practically prohibitive. It is also enacted that the reasonable requirements of the public shall not be deemed to have been satisfied if, by reason of the default of the patentee to manufacture to an adequate extent, and supply on reasonable terms the patented article or any parts thereof necessary for its efficient working, or to carry on the patented process to an adequate extent, or to grant licenses on reasonable terms, any existing trade or industry, or the establishment of any new trade or industry, in the United Kingdom, be unfairly prejudiced, or the demand for the patented article, or the article produced by the patented process be not reasonably met; or if any trade or industry in the United Kingdom be unfairly prejudiced by the conditions attached by the patentee, before or after the passing of the Act, to the purchase, hire, or use of the patented article, or to the using or working of the patented process.

Sales, Leases, and Licenses.—In any contract made after the passing of the Act in relation to the sale or lease of, or license to use or work, any article or process protected by a patent, any condition will be null and void that will either (*a*) prohibit or restrict the purchaser, lessee, or licensee from using any article or class of articles, whether patented or not, or any patented process, supplied or owned by any person other than the seller, lessor, or licensor, or his nominee; or (*b*) require the purchaser, lessee, or licensee to acquire from the seller, lessor, or licensor, or his nominees any article or class of articles not protected by the patent. The provision, however, is not to apply if the seller, lessor, or licensor, prove that at the time when the contract was entered into the purchaser, lessee, or licensee had the option of purchasing the article or obtaining a lease or license on reasonable terms, and without such objectionable conditions; and if, also, the contract entitle the purchaser, lessee, or licensee to relieve himself of his liability to observe the objectionable conditions on giving the other party three months' notice in writing, and on payment of such compensation as may be fixed by an arbitrator appointed by the Board of Trade.

Any contract made before the passing of the Act, and containing conditions that would be null and void under this provision had the contract been made after the passing of the Act, may be determined by either party on giving three months' notice in writing to the other party, subject to the payment of such compensation as, failing agreement, may be awarded by a Board of Trade arbitrator.

An action for infringement can be defended on the ground that, after the passing of the Act, the patentee inserted into a contract relating to the patent and still in force a condition of the kind above defined.

It should be noted that it is not unlawful to insert a condition whereby a person is prohibited from selling any goods other than those of a particular person, or whereby the lessor or licensor reserves to himself or his nominees the right to supply such new parts of the patented article as may be required to put or keep it in repair.

Any contract relating to the lease of or license to

use or work any patented article or patented process, whether made before or after the passing of the Act, may, when the article or process is no longer protected by a patent, be determined by either party on giving three months' notice in writing to the other party; but in the case of any contract made before the passing of the Act, such determination is subject to the payment of compensation.

It is no secret that the section in question was chiefly aimed at the methods of the American Trusts, one of which, according to Mr. Lloyd-George, has practically compelled the boot industry in this country to employ their machines exclusively, and has obtained contracts with the manufacturers such that if an improvement on the invention to which the contracts relate, were taken up at the end of nineteen years, the trade would be bound to take the improvement, and renew their leases for another twenty years, and so forth, apparently *ad infinitum*. It was consequently necessary in the opinion of the Government to protect this very powerful industry, and to say that this country really could not stand the use of a privilege conferred by the Crown for the purpose of hampering a whole trade.

Opposition to Grant.—In addition to the present ground of opposition, the grant of a patent is to be opposable on the ground that the invention has been claimed in a complete specification that will be dated prior, but not more than fifty years prior, to the patent the grant of which is opposed, or on the ground that the nature of invention, or the manner in which it is to be performed, is not sufficiently or fairly ascertained in the complete specification. The former of these two new grounds is to enable the grant of a patent to be opposed on the basis of an application made in this country, and founded, under the International Convention, on a prior application made abroad.

Revocation and Defence of Infringement Actions.—Any person who would have been entitled to oppose the grant of a patent, or the successor in interest of such a person, may, within two years from the date of the patent, apply to the Comptroller for its revocation on any ground on which the grant of the patent might have been opposed; but the leave of the Court is requisite when an action for infringement or proceedings for revocation are pending in the Court. The decision of the Comptroller is to be subject to appeal to the Court.

Any ground on which a patent may be revoked by the Comptroller, or, as an alternative to the grant of a compulsory license on the ground that the reasonable requirements of the public with respect to the patented invention have not been satisfied, is to be available as a defence to an action for infringement, or as a ground for revocation by petition to the Court.

In an action for infringement a defendant entitled to present a petition to the Court for the revocation of the patent may alternatively counter-claim for revocation.

Remedies for Non-payment of Fees.—If a sealing fee have not been paid within the prescribed time, whether or no that time have expired before the end of 1907, the Comptroller may, subject to the prescribed payment, extend the time for the payment of the sealing fee.

If a patent have become void through the non-payment of a fee within the prescribed time, unless the omission were intentional and undue delay occurred in making the application, the Comptroller may, after giving an opportunity for opposition to the application, issue an order restoring the patent; but persons who may have availed themselves of the patented subject-matter after an official announcement of the voidance of the patent are to be protected.

Disconformity.—If any examiner report that an invention described in a complete specification is not substantially the same as that described in the provisional specification, the Comptroller may, with the consent of the applicant, cancel the provisional specification, and treat the application as having been made on the day on which the complete specification was left; but where the complete specification is in disconformity only by reason of the insertion of additional matter, the claim for the additional matter may be treated as an application for that invention made at the filing of the complete specification, and the original application may be allowed to proceed so far as concerns the invention covered by both specifications.

A patent is no longer to be held invalid on the ground that the complete specification claims an invention additional to or different from that contained in the provisional specification, provided that the additional or different invention were novel at the filing of the complete specification, and that the applicant were its first and true inventor.

Concurrent Applications.—If the same applicant have obtained concurrent provisional protection on separate applications for inventions which are cognate, or modifications one of another, the Comptroller may, if of opinion that they can be properly covered by a single patent, accept a single complete specification in respect of the whole of such applications. The single patent granted is to bear the date of the earliest application; but in considering the validity of the patent, and for the purposes of opposition, regard is to be had to the respective dates of the several provisional specifications.

Before availing himself of this provision, an applicant should carefully consider whether, for the sake of the saving in fees, it would be worth while to run the increased risk of invalidation, which, of course, is often proportional to the number of inventions covered by a patent.

Patents of Addition.—A person having applied for or obtained a patent, may, in respect of any improvement or modification of the invention, apply for what is called a patent of addition, which will have the advantage that no renewal fees will be payable thereon, but the disadvantage that it will remain in force only as long as the patent for the original invention.

Nothing is said as to what would happen should no patent be granted for the original invention, and it should be noted that in most cases a patent of addition would probably give to the patentee no further protection than would be accorded by the original patent.

Chemical Inventions.—In the case of a chemical invention, the Comptroller may require typical samples and specimens to be furnished before accepting the complete specification.

This provision has been inserted with the object of preventing patents from being obtained for ideas that are merely nebulous, and thus to prevent persons from being hampered who have first conceived means for bringing such ideas to practical success.

Prolongation of Patents.—Hitherto, to obtain the prolongation of a patent, it has been necessary to present a petition to the King, and the petition has been referred to the Judicial Committee of the Privy Council, with the result that the obtaining of an extension of the term of a patent has been a very costly matter. After December 31st next, a patentee may, at least six months before the time at which the patent would ordinarily expire, present a petition for its extension to the Supreme Court. It is, therefore, to be hoped that the cost of securing such extensions will be materially reduced.

Anticipation.—Prior publication of an invention or any part thereof, if the matter published were derived or obtained from the patentee and published without his knowledge and consent, is no longer to be a ground for the voidance of a patent, provided that the patentee, after learning of the publication, applied for and obtained protection for his invention with all reasonable diligence.

Innocent Infringers.—No damages can be recovered for infringement of a patent granted after December 31st next from any person proving that at the date of the infringement he was unaware, and had no reasonable means of making himself aware, of the existence of the patent. The application to a patented article of a word indicating that a patent has been obtained is not to be deemed to constitute notice of the existence of the patent, unless the year and number of the patent be added.

Official Search.—After a date to be fixed by the Board of Trade, every official search as to the novelty of the subject-matter of an application for a patent is to extend to specifications pertaining to prior publications but published after the date of the application under investigation, and if it appear that the invention is wholly or in part claimed in any specification so published, the applicant, whether or not his specification have been accepted or a patent granted to him, is to be afforded facilities for amending his specification, and failing his doing so the Comptroller will determine what references, if any, ought to be made in the specification by way of notice to the public. An application is be regarded as prior to another if a patent granted on the former would be of prior date to a patent granted on the latter; this will enable the specifications of applications filed here subsequently to an application under investigation, but based under the International Convention on prior applications made abroad, to be included in the investigation.

Refusal of Anticipated Applications.—In lieu of requiring references to be made in an applicant's specification as a result of an official search, the Comptroller may, after the 31st of December next, refuse to grant a patent; but he can do so only if satisfied that the invention claimed has, in some specification to which the official investigation has extended, been wholly and specifically claimed.

Inventions of Deceased Persons.—The limit of six months, within which an application for a patent for an invention for a person deceased must be made by his representative, is to be removed.

Fraud.—A patent granted to an inventor in lieu of a patent revoked on the ground of fraud, is to bear, instead of the date of revocation, the date of the revoked patent, but no action is to be brought for any infringement of the patent so granted committed before the date of the actual grant of the substitutional patent. The alteration in the dating of the substitutional patent is important from the point of view of priority.

Joint Grantees.—Under the present law the grant of a patent to joint applicants gives a joint interest which passes to the survivor or survivors, unless there has been a severance of that interest, and each patentee can retain any profits he may make by working the invention himself, though it is questionable whether if he grant licenses, he will not be accountable to his co-patentees for the royalties obtained. Under the new law, unless otherwise specified in the patent, joint grantees are to be treated for the purpose of the devolution of the legal interest as joint tenants, but, subject to any contract to the contrary, each, whilst being entitled to use the invention for his own profit without accounting to the others, is not to be entitled to grant a license without their consent, and on his death his beneficial interest is to devolve on his personal representative as part of his personal estate.

Instruments or Munitions of War.—The provisions hitherto in force in regard to the acquisition of inventions and patents for improvements in instruments and munitions of war, and keeping secret corresponding specifications by the Secretary of State for War, are to apply also to the Admiralty, and it is enacted that, for the purpose of insuring secrecy with respect to such patents, rules may be made modifying previous provisions of the law.

PART II.—DESIGNS.

Abandoned and Refused Applications.—An application is to be deemed abandoned if, owing to the default or neglect of the applicant, registration have not been effected within the prescribed time. If an application have been abandoned or refused, the application and any drawings, photographs, tracings, re-

presentations, or specimens left in connexion therewith are not at any time to be open to public inspection or to be published by the Comptroller.

Period of Copyright.—On application within the prescribed time before the expiration of the original five years of copyright and on payment of the prescribed fee, the Comptroller is to extend the period of copyright by a further five years, and on application within the prescribed time before the expiration of the second period of five years, the Comptroller may, on payment of the prescribed fee, extend the period by another five years.

Prior Publication.—The confidential disclosure of a design by the proprietor, and the disclosure of a design in breach of good faith by any other person, and the acceptance of a first and confidential order for goods bearing a new or original textile design intended for registration, are not to be deemed to be publication of the design sufficient to invalidate its copyright if registration be obtained subsequently to the dislosure or acceptance.

Marking.—According to the law now in force, failure to apply the prescribed indication of registration will cause the copyright to cease unless the proprietor shew that he took all proper steps to insure such marking. Under the new law, failure to act in this manner is not to entail the loss of the copyright, but in the event of any such failure the proprietor is not to be entitled to recover any penalty or damages for infringement, unless he shew that he took all proper steps to insure the marking of the articles, or that the infringement took place after the person guilty knew or had received notice of the existence of the copyright.

Where representation is made to the Board of Trade by or on behalf of any trade or industry that in its interests it is expedient to dispense with or modify, as regards any class or description of articles, any of the requirements as to marking, the Board may dispense with or modify such requirements.

Designs used Wholly or Mainly Abroad.—The provisions of the Act respecting the revocation of patents for inventions worked exclusively or mainly outside the United Kingdom, are, with the necessary modifications, to apply to the cancellation of the registration of designs, except that an application for cancellation may be made to the Comptroller at any time after the registration of a design, and that there is to be no appeal from the decision of the Comptroller.

An action for infringement of the copyright of a design may be defended on the ground that the design is used for manufacture exclusively or mainly outside the United Kingdom.

Anticipation by Prior Registration.—The application of the proprietor of a design already registered in respect of one or more classes is not to be refused, and its registration is not to be invalidated, on the ground that the design was so previously registered, or on the ground that the design had been previously published in the United Kingdom by reason of its application to goods in respect of which it was previously registered.

Inspection of Designs.—A shorter period than the existence of the copyright of a design, but not less than two years from the registration of the design, may be prescribed for the general prohibition of the inspection of a design and taking of copies thereof, and different periods may be prescribed for different classes of goods.

PART III.—GENERAL.

Branch Offices.—Provision is made for the establishment of branch offices for designs at Manchester or elsewhere, and for the leaving of any document, or the doing of anything, at any branch office that may be established, instead of at the Patent Office.

Registers.—It is directed that entries shall be made in the registers in regard to mortgages, licenses, and other interests in patents and designs. Modification is also made in the provisions as to the rectification of registers.

Errors in Patents.—The Comptroller is empowered, on applicetion and on the payment of the prescribed fee, to correct clerical errors in patents.

Excluded Days.—The previsions of the law now in force with regard to Bank Holidays and other days on which the Patent Office is closed, are extended by an enactment to the effect that if the last day fixed by the Act for doing anything fall on any day specified in rules under the Act as an excluded day, the rules may provide for the doing of the thing on the next following day that is not an excluded day.

False Marking of Designs.—If any person, after the expiration of the copyright in a design, put on any article to which the design has been applied any words implying the subsistence of the copyright, he will be liable on summary conviction to a fine not exceeding five pounds.

Royal Arms.—The grant of a patent under the Act will not authorize the patentee to use the Royal Arms in any way.

Appeals and Petitions to the Court.—Every appeal from a decision of the Comptroller to the Court, and every petition referred to or presented to the Court, is to be made, referred, or presented to a Judge of the High Court selected for the purpose by the Lord Chancellor, and the decision of that Judge is to be final, except in the case of an appeal from a decision of the Comptroller revoking a patent on any ground on which the grant of the patent might have been opposed.

Evidence before Comptroller. — In proceedings before the Comptroller, evidence is, in the absence of directions to the contrary, as before, to be given by statutory declaration; but, if he think it right to do so, the Comptroller, who is empowered to administer oaths for the purpose, may take evidence *vivâ voce*, and may allow any person to be cross-examined on his declaration.

Costs before Comptroller and Law Officer.—In proceedings before the Comptroller relating to an opposi-

tion to the grant of a patent or to the amendment of a specification, or relating to the revocation of a patent, the Comptroller is to have power to award reasonable costs and to direct how and by whom they are to be paid.

If a party giving notice of opposition to the grant of a patent, or applying to the Comptroller for the revocation of a patent, or giving notice of an appeal from any decision of the Comptroller, neither reside nor carry on business in the United Kingdom or the Isle of Man, the Comptroller or the Law Officer respectively may require the party to give security for costs.

Title "Patent Office."—Any person using the title "Patent Office," or any other words suggesting that his place of business is officially connected with, or is, the Patent Office, is to be liable on a summary conviction to a fine not exceeding twenty pounds.

Agents.—Provision is made for authorizing the Comptroller to refuse to recognize as agent any person whose name has been erased from the Register of Patent Agents, or who would have rendered himself liable to have had his name so erased had his name been on the register; or any company which, had it been an individual, the Comptroller could refuse so to recognize; or any company or firm having as director, manager, or partner, any person whom the Comptroller could refuse to recognize as agent.

The Comptroller is to refuse to recognize as agent any person neither residing nor having a place of business in the United Kingdom or the Isle of Man.

Repeal.—In this article it has been endeavoured to indicate, of course, merely the important alterations of the law resulting from the Act, but the Act will ultimately take the place of the whole of the Acts relating to patents and designs (except the Statute of Monopolies) now in force; and the only portions of those Acts which will not automatically cease to be in force on January 1st next, are those relating to the procedure for the revocation of a patent on petition to the Court and in an action for infringement, and to the procedure on an application for the registration of a design, which will be repealed as from the date when rules dealing with the matters in question come into operation.

Orders in Council, rules, and tables of fees now in force are not, however, repealed, but it should be noted that, under the schedule of fees to the Act rules may be made according to which the cost of renewal may be increased, so that, at most, fifty pounds may be charged for the renewal of a patent before the end of four years, and a further hundred pounds for its renewal before the end of eight years from the date of the patent, or, in lieu of the fifty and hundred pounds just mentioned, an annual fee of ten pounds before the expiration of the fourth, fifth, sixth, and seventh years, fifteen pounds before the expiration of the eighth and ninth years, and twenty pounds before the expiration of the tenth, eleventh, twelfth, and thirteenth years.

EMIGRATION.

The Statistical Tables relating to emigration from the United Kingdom in 1906 show that the balance outward of British and Irish passengers—which may be taken as roughly representing the number of British and Irish emigrants properly so-called—viz., 194,671, was greater than in any year since 1887. And it is very noticeable that notwithstanding the revolution in land tenure in Ireland caused by the legislation of the last thirty years, and the gradual, and even rapid, conversion of the Irish tenantry into cultivating owners, emigration from Ireland shows few signs of substantial abatement. It is true that the proportion of Irish emigrants to the total of all British and Irish emigration has fallen from 47 per cent. in the quinquennial period 1866-70 to 16 per cent. in 1906. But then the relative populations of England, Scotland, and Ireland must be borne in mind. Whilst the population of England and Scotland has shown continuous and rapid growth that of Ireland has steadily decreased. Last year the total number of Irish emigrants was 52,210, and in 1893 the numbers were almost identical, namely, 52,130. A peculiarity of Irish emigration is the large proportion of women. In each of the years 1893 to 1905 the number of women actually exceeded the number of men, and last year the difference was not great in favour of the men, who numbered 27,420 as against 24,790 females. Again the relatively low proportion of children is noticeable, only 8 per cent. of the outward emigrants, of Irish origin, being children under twelve. Of a total emigration from Scotland of 53,162, 7,716 were children under twelve years of age; of a total emigration from Ireland of 52,210, only 4,103 were children under the same age. The total emigration from England last year was considerably higher—219,765—than in any previous year—in 1905 it was only 170,408—and its percentage of the total from the United Kingdom—68 per cent.—exceeded that of any previous year by 3 per cent. For the first time since these statistics began to be compiled, the number of Scotch emigrants was larger than the number of Irish—53,162 as against 52,210.

As to the destination of the emigrants, it should be remembered that the information which the Board of Trade have the statutory power to obtain only shows the places at which the emigrants propose to disembark, and not necessarily their ultimate destination. It is known that a large number of emigrants who contract to land at ports in British North America, proceed immediately to the United States, and that, on the other hand, many of those who contract to land at United States ports, proceed at once to British North America. The voluntary returns supplied to the Board of Trade by the courtesy of the various shipping companies lead to the conclusion that the statutory returns under-estimate the number of British emigrants to British North America. The British and Irish emigration to British North America has increased from 18,443, or 11 per cent., in 1900, to 114,859, or 35 per cent., in 1906, whereas the emigra-

tion to Australasia has fallen proportionately from 14,922, or 9 per cent., in 1900, to 19,331, or 6 per cent., in 1906. To the Cape of Good Hope, taking the same period, the figures are 20,815 and 22,804, the percentage falling from 12 to 7. Turning to occupations, the following figures show the occupations of the male emigrants from the United Kingdom in 1906:—Agricultural, 25,473; commercial and professional, 17,612; skilled trades, 39,285; labourers, 50,544. And of females the occupations of the majority were—Domestic and other service, 22,617; dressmakers and other trades, 3,392; teachers, clerks, and professions, 1,656; no stated occupation, 77,474.

Table No. 5 gives some suggestive figures as to emigration to the United States. Twenty years ago of a total emigration to that country of 334,203, 112,539 came from the United Kingdom. In 1906 the total had risen to 1,100,735, and of these only 102,193 came from the United Kingdom. But if the proportion of British emigrants to the United States has shrunk from about 1 in 3 to less than 1 in 10 the shrinkage in German emigration is even more remarkable. In 1886 84,403 emigrants went to the United States from Germany, in 1906 only 37,564. So with Sweden, Norway and Denmark. In 1886 the total number of emigrants was 46,735, in 1906 it was indeed larger but not much at 52,781. On the other hand, taking the same years, the Italian emigration increased from 21,315 to 273,120; the Austro-Hungarian from 28,680 to 265,138; the Russian and Poles from 21,739 to 215,665. These figures show the profound change in the character of the emigration to the United States during the last twenty years, a change that Americans can hardly look upon with anything approaching satisfaction. The number of emigrants rejected by the United States in 1906 was 446, "paupers or likely to become a public charge" accounting for 286 of them, and "idiocy or insanity" for 97 of the remainder.

OUT-DOOR ADVERTISING IN BRAZIL.

In Brazil, it may be said generally, that anything which can be made to produce a municipal revenue is employed to that end. For instance, the financial estimate of the municipality of Rio de Janeiro for the current year includes revenues from a tax on salaries of officials, revision of house numbers, wagon weighing tax, registration of cows, domestic servant tax, tax on unoccupied building sites, fines for infractions of contracts, &c. Among such estimates are those for rent and licences of kiosks, and advertisement and door-plate tax, which concern out-door advertising. Every sign in Rio is taxed. The American Consul there says that the proprietor of a café, having a special *sorvete*, or ice, to serve, makes a placard and hangs it to a door-post, or to one of the palm trees in tubs which commonly decorate such establishments. The notice thus posted must have a revenue stamp attached. Permanent signs are taxed on a permanent basis, temporary signs on a stamp basis. A sign "house to be let," bears a revenue stamp. Under such circumstances the tax on sign-boards or bill-boards is the expected thing, but naturally there is much less general use of such forms of advertising. As in cities in England and the United States, a vacant corner in a frequented street is very likely to have some sort of a bill-board arrangement, and temporary hoardings about buildings in course of construction are generally covered with more or less prominent advertisements, but these advertisements being taxed, are regulated both in size and other respects. Since it costs in Brazil a good deal in the way of taxes, as well as in the preparation of boards, for the purpose of such advertisements, there are very few of them to be found. The outdoor signs are, as a rule, painted signs, and in general it may be said that they represent the best form of poster or billboard advertising. Theoretically, anyone can erect outdoor signs, subject to the approval of the prefect or mayor of the municipality and paying the tax, but practically the erection of such signs is almost altogether in the control of a company which has taken possession of the most available sites for such work. In a large number of suitable positions in parks, pleasure resorts, vacant street corners and elsewhere, kiosks have been erected for the sale of light refreshments, and these structures are taken advantage of for advertising purposes. As a rule, the kiosk privilege carries with it the advertising privilege. There are also in the various streets and avenues small movable kiosks, often of so light a construction that the proprietor carries it about with him, goods and all. These are also licensed by the municipality and generally carry advertising matter. In the way of electric signs there is practically nothing to be seen in most Brazilian cities. The consul says that he does not know of a single electric sign in Rio de Janeiro, but it is probable that as soon as the new electric light and power service is effective there will be a change, and that regulations will be modified to meet changed conditions. In Sao Paulo, in some respects the most up-to-date city in Brazil, there is plenty of electrical current to be had at comparatively low rates, and electric signs are commencing to appear.

THE MINERAL INDUSTRIES OF CANADA.

According to the "Annual Report on the Mineral Industries of Canada," recently issued by the Geological Survey of Canada, the great total of the mineral production of the Dominion in 1905 was valued at £14,500,000. In 1904, as compared with 1903, there was a shrinkage of about 2·7 per cent., and not only has this falling off been made up, but the increase in 1905 over 1904 amounts nearly to £2,000,000, or about 16 per cent. The uniform basis of valuation adopted enables a comparison to be made, and it is found that the total for the year 1905 is just about 8,300,000 greater than in 1895, or

a growth of 200 per cent. Substantial increases in 1905, as compared with 1904, are shown by all the leading mineral industries, except in the case of gold, in which a very considerable falling off has to be recorded. This is altogether due to the continued decrease in the production of the Yucon placers, which has been continuous now for some years. This shrinkage has been offset by increases in all the other gold mining districts of the country, amounting to about £62,000. The actual gold output of Canada in 1905 was valued at £3,041,000, as compared with £3,430,000 in 1904—a decrease of 11 25 per cent. The gold production has steadily decreased since 1900, when a maximum output of £5,800,000 was reached, the falling off being due in the main to the gradual lessening of the output of the Yukon placer deposits, which reached their highest production in the year mentioned. The other gold-producing districts of Canada all show increases on 1905. Of the total output 57 per cent. was derived from the Yukon district, and 96 per cent. from the Yucon and British Columbia combined. Nearly 64 per cent. of the whole was obtained from placer and hydraulic working, &c., and 36 per cent. from lode mining. The quantity of gold produced by provinces and districts in 1905 was as follows:—North-West Territories, Yukon district, 402,864 ounces fine; Saskatchewan River, 121; British Columbia, 285,554; Nova Scotia, 13,708; Quebec, 191; and Ontario, 4,403, making a total of 706,841 ounces fine, valued, as stated above, at £3,041,000. Silver is produced in Canada in the provinces of Quebec, Ontario, and British Columbia, and a certain quantity is also recovered from the placer-gold found in the Yukon. The total output in Canada in 1905 was 5,994,292 ounces, valued at £753,000, an increase in quantity of 2,416,766 ounces, or 67 per cent., and in value of £327,000, or 76 per cent. compared with the output in 1904. This large increase is due in a measure to the doubling of the output of argentiferous lead ore from East Kootenay, British Columbia, but chiefly to a large output from the recently opened up native silver deposits at Cobalt, Ontario. Since 1894 the argentiferous lead ores of British Columbia have been responsible for the greater part of the silver output in Canada, over 90 per cent. being obtained from that province. In 1905, however, the large silver production at Cobalt, Ontario, has somewhat reduced the relative importance of the western province in the total output. The proportions in that year were Ontario nearly 41 per cent., British Columbia 57 per cent. The most valuable of the mineral assets of Canada is coal, which stands pre-eminent; and if to this be added the other fuel items, viz., petroleum and natural gas, 27 per cent. of the total mineral production is accounted for. For the year ending December 31, 1905, Canada's coal production amounted to 8,667,948 tons, valued at £650,000, to which Nova Scotia contributed 5,646,583 tons; British Columbia, 1,945,452 tons; North-West Territories, including Yukon, 1,046,513 tons, and New Brunswick, 29,400 tons. The new provinces of Alberta and Saskatchewan have been advancing, as coal producers, at a very rapid rate. Nova Scotia has remained practically stationary since 1903, while in New Brunswick the coal industry has shown signs of great activity as compared with previous years. Here the production has increased from 9,000 tons in 1904 to over 29,000 tons in 1905. Of copper, the total amount produced in 1905 was 48,092,753 pounds, valued at £1,600,000, and this is the highest output yet recorded, being an increase over 1904 of 6,709,031 pounds, or 16·21 per cent., and more than twice the output of any year previous to 1901. The production by provinces was as follows:—Quebec, 1,621,243 pounds; Ontario, 8,779,259, and British Columbia, 37,692,251 pounds. It will thus be seen that of the total output, British Columbia contributed in 1905 over 78 per cent., Ontario over 18 per cent., and Quebec a little over 3 per cent. The production of lead showed a total output in 1905 of 56,864,915 pounds, as compared with 37,531,244 pounds in 1904, an increase of 19,333,671 pounds, or 51 per cent. The high price of refined lead on the New York market during 1905, together with the bounty paid in Canada on the production of lead ores, no doubt stimulated the production of the metal, although the output was not as great as was attained in 1900, when 63,169,821 were produced without the assistance of any bounty, and when the price of lead was lower than during 1905. The whole of the output of lead in 1905 was derived from mines in British Columbia, with the exception a small amount which was mined in Ontario. The production of nickel (contents of matte shipped) from the copper nickel ores of the Sudbury district of Ontario, reached a total of 18,876,315 pounds in 1905, the largest output ever reached in the district, being more than twice the production of 1901, and an increase of 8,328,432 pounds, or nearly 79 per cent. over 1904. The value of the production was £1,573,000. Asbestos was produced to the extent of 50,669 tons, valued at £310,000, and asbestic 17,594 tons, valued at £3,500. According to the returns, there are three main grades of the product, viz., crude, mill-stock, and asbestic. The former represents the portions of clean fibre picked out by hand; the mill-stock, as its name implies, represents a number of different products of the milling process; whilst the by-product, for which the name asbestic has been adopted, consists of the residual serpentine sand, carrying a large proportion of very short fibre. This finds a sale for plastering and other uses, taking the place of the ordinary sand and hair, over which it is claimed to have many advantages. The asbestos fibre is sold to manufacturers, who produce with it a great variety of finished articles, millboard paper, woven goods, &c., for use, where a fireproof and non-conducting material is called for. The asbestos product of Canada comes altogether from one small district in the eastern townships of Quebec province.

HOME INDUSTRIES.

Capital and British Railways.—The Blue-book on the Railways of the United Kingdom during the year 1906, just published, shows that the increase in the authorised capital of British railway companies during the year was very much the lowest on record, being only, in round figures, £2,500,000 sterling. The previous minimum was £7,600,000 in 1885. The total capital invested in British railways at the end of 1906 was £1,286,900,000. It may be assumed that the very slight increase in capital during 1906 was mainly due to the adverse condition of the money market, but also to a growing caution in expenditure on new works which is noticeable in the management of most of the great railway companies.

Cotton Production.—It is not surprising that the Lancashire cotton spinners who have been travelling through the Cotton States have found the planters and others desirous to satisfy them that they need not go further afield for their cotton supplies, and that the Southern States of America can easily meet the world's growing demand for cotton. At many gatherings this was emphasised in American speeches, and supported by undisputed statistics. For example, Governor Hoke Smith, when welcoming the Lancashire spinners in Atlanta, said that less than one-fifth of the land of the State is in cultivation and not more than half of that in cultivation is in cotton. "We ask," said the Governor, "your attention to our claim, that while cotton may be grown with partial success in many countries of the world, yet nature has intended this to be the permanent section for the growth of cotton in its perfection. This is not due to better knowledge of the culture, but to a combination of soil and climate that exists nowhere else. . . . . You can rely upon our cotton belt to furnish a supply as a permanent proposition to meet your ever-increasing demand." Granted that cotton cannot be grown elsewhere in such perfection as in America —a proposition by no means demonstrated—and that the Southern States can continue to meet the requirements of the world, the reasons which led to the formation of the British Cotton Growing Association remain. It may be true that only a comparatively small area of land in the South is under cotton cultivation, that enormous areas are still available for the staple, and that the South can produce all the cotton the world can require. Lancashire can never feel really safe whilst she has to depend so largely as she does to-day upon a single country for the raw material of her leading industry. The livelihood of 2,500,000 people is involved in getting raw cotton at prices not above certain figures, and only four years ago Lancashire was suffering from the high price of cotton, which compelled the reduction of working hours from 55½ to 40 a week, a reduction that continued for nearly a year. Any day there may be a repetition of these fictitious figures whilst the sources of supply remain so limited as at present. The cultivation of cotton is steadily spreading within the Empire, and although the expansion is less rapid than might be wished, it is continuous, and in encouraging and assisting it, the British Cotton Growing Association is doing a national work of great value.

Marine Engineering in London.—Messrs. Humphrys and Tennant, of Deptford Pier Works, have decided to follow Messrs. Yarrow in closing their establishment upon the Thames when present orders are completed. Messrs. Humphrys and Tennant have maintained their position in the front rank of marine engineering until the end. Their last Admiralty contract, now nearly completed, has been for the turbine machinery and water-tube boilers of the *Invincible*, building at Elswick. The power to be developed exceeds 40,000 horse-power. Whilst Messrs. Humphrys' work has been most closely associated with the Royal Navy, they have done important work for the mercantile marine. Their retirement from the Thames is due, as was that of the Messrs. Yarrow, to their conviction that the time has come when the struggle to maintain their place in competition with other firms more favourably situated, is not worth continuing. In a letter to *The Times* they point out the causes which have led them to their decision. (1) Wages are much higher in London than in any other district in Great Britain. (2) Coal and material cost much more. (3) Rates are much higher. Perhaps, they say, the first and third of these are the more important from an engineer's point of view. Wages are higher now than they have ever been, and may be said to be abnormally high. Rates also are much higher. Messrs. Humphrys, Tennant and Co. allege that London municipal authorities "fail to grasp the importance of doing what they can to assist industrial enterprises which are the source of very great benefit to the district in which they are situated; they seem to be imbued with the idea that the more they can extract from the unfortunate employer the better. Take for example their action during the last quinquennial assessment, when, making use of the vagueness of the wording of the law relating to assessment of machinery, they very largely increased all assessments and so placed an additional burden upon the users— in our case amounting to over 33 per cent. on one assessment and over 50 per cent. on another." There may be a sufficient answer to these complaints, but the fact remains that the great engineering firms are leaving the London district, and that the continuance of this migration must be a very serious matter for London workmen, not to speak of other sections of the community.

Iron and Steel Production and Consumption.—The annual return of the Board of Trade showing the consumption and production of iron and steel in the United Kingdom and the principal foreign countries in recent years has just been issued. Practically complete information is given for 16 years to 1905, and

in many cases it has also been possible to give figures for 1906. The total output of iron ore in the world amounted in 1905 to about 114 million tons, the principal producers being the United States, Germany, and the United Kingdom. In that year the total production of the United States was 42,520,000 tons, of Germany 23,067,000 tons, and of the United Kingdom of 14,591,000. The preliminary figures so far available for 1906 indicate a further large increase in the output of the United States, the total being rather under 50 million tons, or 7 million tons more than in 1905. In Germany there was an increase of over 3 million tons, and in the United Kingdom of one million. The total quantity of pig iron produced in the world in 1905 amounted to about 55½ million tons, the principal producers being the same three countries in the order named above, the three together accounting for about four-fifths of the total output of the world. The total production of the United States was 22,992,000 tons, of Germany 10,700,000 tons, and of the United Kingdom 9,608,000 tons. During 1905 the production of the United States increased by no less than 6½ million tons, the production of the United Kingdom and Germany increasing by 900,000 tons and 800,000 tons respectively. The preliminary figures so far available for 1906 indicate that in that year there was an increase of 540,000 tons in the production of the United Kingdom; of 1,400,000 tons in the production of Germany; and of over 2¼ million tons in the production of the United States. At present the greater proportion of the pig iron consumed is utilised in the production of steel, the use of steel having increased very markedly in recent years. The total steel production of the world in 1905 was about 43,000,000 tons, of which 20,024,000 tons must be credited to the United States, 9,905,000 to Germany, and only 5,812,000 to the United Kingdom. Preliminary figures for 1906 indicate there was a further large increase in the production of the United States, which reached about 23,750,000 tons, whilst the production of Germany increased by about a million tons, and that of the United Kingdom by about two-thirds of a million tons.

Merchant Shipping.—Some indication of the enormous growth of shipping enterprise during the last half century may be gathered from a return just issued by the Board of Trade, and which shows that the total tonnage of sailing and steam vessels of different nationalities entered and cleared in the foreign trade at ports in the United Kingdom increased from 24,690,000 tons in 1860 to 120,790,000 tons in 1906. The proportion of British tonnage to the whole during this period of nearly fifty years has not varied very greatly. It ranges from 56·4 to 72·9 per cent., while the latest figures available give a proportion of 63·3 per cent. During the same time the total tonnage of the merchant navies of the British Empire, including the Colonies, has advanced from 5,711,000 tons to 12,791,000 tons. No other country has exhibited a similar expansion, but Germany shows a slightly larger relative increase. Since 1870 the German mercantile fleet has increased from 982,000 tons to 2,515,000 tons. On the other hand, the tonnage of ships registered in the United States for over sea traffic has shown a remarkable decrease, amounting to no more than 939,000 tons in 1906 as compared with 2,546,000 in 1864. That Great Britain is still maintaining her supremacy is also shown by the record of gross additions to tonnage, which, in the case of the United Kingdom amounted last year to 954,000 tons, the next largest total being furnished by the United States, which added 418,000 tons, including, however, barges and canal boats. On the whole, the figures given in the Return show that Great Britain is holding her own in this department of industry; but there is an unsatisfactory feature, namely, the increasing proportion of foreigners (exclusive of Lascars) employed on British ships. The total in 1906 was 38,000, against 188,000 British subjects, the proportion being 20·22 per cent., a slightly lower percentage indeed than that of 1903, when the proportion was 22·88 per cent., but a great advance upon the figures for earlier years.

The Wheat Trade.—Not only are the present high prices for wheat likely to be maintained, the indications point to enhanced values. There was indeed a decline in American values last week of from 1s. to 1s. 6d. per quarter, but this was due almost entirely to financial panic there. America will have comparatively only a small surplus for export, and much of it has already come over. Between August 1 and September 24 last we received from the United States and Canada 5,930,000 quarters, as against 5,660,000 quarters in the corresponding period of last year, and this notwithstanding the smaller available surplus this year. The explanation may be found in the high prices and monetary stringency. The shipments from Russia and the Danubian ports show a great falling off. Taking the same period they amounted for the present year to only 4,925,000 qrs. as against 6,400,000 qrs. in the corresponding period of 1906, and 10,150,000 qrs. in 1905. Only comparatively small supplies are to be expected from Russia this season, and up to the present the supplies from Argentina have been very small only (taking the same period as above) 620,000 qrs. as against 975,000 qrs. in 1906 and 1,900,000 qrs. in 1905. Advices from Australia make it very doubtful whether there will be any surplus for export to Europe. It seems certain, therefore, that home farmers who can hold their wheat will be the gainers, for nearly every wheat-producing country in the world seems to have had abnormal weather conditions this year, causing, of course, a widespread shortage. Usually when the supplies from one country run short an abundance in another makes up the deficiency, but the United States, Canada, Russia, India, Australasia, all are short,

Argentina being the one possible exception, and there the harvest has still to be gathered. And it is to be noted that whilst harvests in Europe have been poor, there is a growing demand on the Continent for wheat flour. The labouring classes in Continental cities are beginning to show preference for white bread to the dark bread made years ago, and growing prosperity is enabling some of them to indulge in the preference.

GENERAL NOTES.

British Trade with Florence.—Commenting upon the trade and commerce of Florence Major Chapman, His Majesty's Consul-General refers (Cd. 3727-9) to one reason why German and other foreign houses seem to be making headway when he says that British houses with few exceptions still insist on terms which are no longer acceptable, as for instance, requiring payment on consignment on home steamer or at station of departure, and sometimes insisting on payment of invoice before consignment, even when dealing with well-known firms. The United States and Germany—especially the latter—are much more liberal in their conditions. British firms should also, in the opinion of the Consul-General, relieve purchasers of the surprises of charges for insurance, transport, freight, customs, &c., as it is better for them to calculate these charges at the place of shipment than to burden the receiver with documents which he finds it difficult to understand, and which do not enable him to check expenses. By so doing, and making reasonable prices, British firms would, the Consul-General thinks, be able to push their manufactures to a much larger extent.

Commercial Travellers in Pernambuco.—In reporting upon the trade and commerce of Pernambuco, Mr. Consul Stanforth (Cd. 3727-5) lays stress upon the need for "suitable representation" if British trade is to be maintained and increased. The number of German travellers who regularly visit Pernambuco greatly exceeds the total number of travellers from all other countries. The Germans secure a large number of orders, and do a very satisfactory business, much of which might be secured, the Consul thinks, by British exporters if they were better represented. Something like half these German travellers represent Hamburg houses dealing in Manchester cotton goods, for which there is a large demand in the district, and it would appear that if the orders were secured direct by British travellers the intermediate profit which now goes to make up so large a proportion of German business in Pernambuco might be secured to British exporters. The same consideration would appear to apply to articles of German manufacture, with which British firms should, in many cases, be able to compete with every chance of success. Other things being equal British manufactures are much preferred by buyers in Pernambuco to those of German or any other origin. The Consul says that not only should commercial travellers have some knowledge of the language, they should be of "agreeable manners and presence, which qualifications possess in Pernambuco a value far beyond what is usually attached to them in ordinary matters of business." The Consul points out, too, that it is very desirable that British exporters to Pernambuco should use only the metric system in their quotations, dealings, and correspondence with import houses there. Brazilians do not understand British weights and measures, and will not take the trouble to convert them; rather than do so they will place their orders elsewhere. The success of German commercial travellers in selling British manufactured goods on behalf of Hamburg houses is to some extent due to their always using the metric system. British exporters should also bear in mind that every Consular invoice should accurately state the contents of each case or package sent to Pernambuco, giving the exact weight and quantity of every article it contains, as well as the material of which it is manufactured. And it must be in accordance with instructions obtained from the Brazilian consulates.

MEETINGS FOR THE ENSUING WEEK.

Monday, Nov. 11...Surveyors, 12, Great George-street, S.W., 8 p.m. Opening address by the President, Mr. Thomas Taylor Wainwright.

Geographical. University of London, Burlington-gardens, W., 8½ p.m. Mr. J. Mackintosh Bell, "The great Douglas Glacier of New Zealand and its neighbourhood."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. F. Hamilton Jackson, "Romanesque Ornaments."

Tuesday, Nov. 12...Asiatic, 22, Albemarle-street, W., 4 p.m. Sir H. Mortimer Durand, "Nadir Shah."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. H. T. Ker, "The Extension, Widening, and Strengthening of Folkestone Pier."

Photographic, 66, Russell-square, W.C., 8 p.m. Discussion on "The Best Methods of Advancing the Study of Photography in Colours."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8 p.m. Mr. R. Jebb, "Twelve Months of Imperial Evolution."

Wednesday, Nov. 13...United Service Institution, Whitehall, S.W., 3 p.m. Captain C. W. Battine, "The Use of the Horse Soldier in the Twentieth Century."

Thursday, Nov. 14...Junior Art Workers' Guild, Clifford's Inn-hall, Fleet-street, E.C., 8 p.m. Mr. Penty, "The Economics of Craftsmanship."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. H. Hill, "The Mind of the Ant."

Friday, Nov. 15...Art Workers' Guild, Clifford's Inn-hall, Fleet-street, E.C., 8 p.m. Paper on "Cups and Flagons."

Architectural Association, 18, Tufton-street, S.W., 7½ p.m. Messrs Gibson and Greenwood, "The Relations between the Architect and the Builder."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Mr. Edward J. Way, "Labour-saving Appliances at the Mines of the New Kleinfontein Co., Transvaal."

Journal of the Society of Arts.

No. 2,869. VOL. LV.

FRIDAY, NOVEMBER 15, 1907.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, W.C.

NOTICES.

H.I.M. THE GERMAN EMPEROR.

At the request of the Council, H.R.H. the Prince of Wales, as President of the Society, graciously invited H.I.M. the German Emperor to become an Honorary Royal Member, and he has now received from His Imperial Majesty the following letter of acceptance :—

Windsor Castle,
12th November, 1907.

SIR,—I have had the honour to receive the letter of November 4th, in which Your Royal Highness asks me to accept the Honorary Royal Membership of the Society of Arts, of which Your Royal Highness is President.

The Society of Arts is an Institution whose work and objects are well known to me, and have always commanded my interest and sincere appreciation. It is with very great pleasure that I accept Your Royal Highness's proposal that my name be added to the list of those Sovereigns who are Honorary Royal Members of the Society, and I beg to thank Your Royal Highness for this mark of kind attention.

I have the honour to be, Sir,
Of Your Royal Highness
the sincerest affectionate cousin and friend,
(Signed) WILLIAM I.R.

ARRANGEMENTS FOR THE SESSION.

The Opening Meeting of the One-hundred-and-Fifty-Fourth Session will be held on Wednesday Evening, the 20th of November, when an Address will be delivered by Sir STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., Vice-President and Chairman of the Council. The Chair will be taken at 8 o'clock. The subject of the Address will be "Lord Clive, and his part in the foundation of the Indian Empire."

Previous to Christmas there will be five Ordinary Meetings, one meeting of the Indian Section, and one of the Applied Art Section.

The following arrangements have been made :—

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock :—

NOVEMBER 27.—"The Franco-British Exhibition, 1908." By THE HON SIR JOHN A. COCKBURN, K.C.M.G. THE RIGHT HON. VISCOUNT SELBY will preside.

DECEMBER 4.—"Old Age Pensions." By Sir EDWARD W. BRABROOK, C.B. SIR WILLIAM BOUSFIELD, LL.D., Member of the Council, will preside.

DECEMBER 11.—"Radio-active Phenomena." (Aldred Lecture.) By SIR WILLIAM RAMSAY, K.C.B., F.R.S. SIR STEUART COLVIN BAYLEY, K.C.S.I., C.I.E., Chairman of the Council, will preside.

DECEMBER 18.—"The Rôle of France in West Africa." By MONSIEUR LUCIEN HUBERT, Député des Ardennes.

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock :—

DECEMBER 12.—"Big Game in India." By REGINALD GILBERT, F.Z.S., late of Bombay.

APPLIED ART SECTION.

Tuesday evening, at 8 o'clock :—

DECEMBER 17.—"How to Make the Most of a Museum." By LEWIS FOREMAN DAY, F.S.A. SIR ASTON WEBB, R.A., F.R.I.B.A., will preside.

SHAW LECTURES ON INDUSTRIAL HYGIENE.

Friday evenings, at 8 o'clock :—

NOVEMBER 29.—The Hygiene of Work in Compressed Air (Diving, Caisson Work, Sub-aqueous Tunnelling, &c.). By JOHN SCOTT HALDANE, M.A., M.D., M.R.C.P. (Edin.), F.R.S. HERBERT LOUIS SAMUEL, M.P., Under-Secretary of State for the Home Department, will preside.

DECEMBER 13.—"Industrial Poisons—Lead and Phosphorus, with special reference to Lucifer Match Making." By PROFESSOR THOMAS OLIVER, M.D.

CANTOR LECTURES.

Monday evenings, at 8 o'clock :—

CONRAD BECK, F.R.M.S., "The Theory of the Microscope." Four Lectures, November 25, December 2, 9, 16.

Meetings after Christmas:—

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock (dates not fixed):—

"Screen-Plate Processes of Colour Photography." By C. E. KENNETH MEES, D.Sc., F.C.S.

"The Problem of Road Construction, with a View to Present and Future Requirements." By H. S. HELE-SHAW, LL.D., F.R.S., and DOUGLAS MACKENZIE.

"Recent Improvements in Decorators' Materials." By A. S. JENNINGS.

"The Underground Water Supplies of the Thames Basin." By CLAYTON BEADLE.

"Industrial Entomology: the Economic Importance of a Study of Insect Life." By F. MARTIN DUNCAN.

"Modern Dairy Practice." By LOUDON M. DOUGLAS.

"War Balloons." By AUGUSTE E. GAUDRON.

"Siam and its People." By HARRY HILLMAN.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

January 16, February 13, March 12, April 30, May 21.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

January 28, February 25, March 24, April 7.

APPLIED ART SECTION.

Tuesdays, at 4.30 or 8 o'clock:—

January 21, February 18, March 31, April 28, May 26.

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

HENRY HARDINGE CUNYNGHAME, C.B., "The Theory and Practice of Clock Making." Six Lectures.

January 20, 27, February 3, 10, 17, 24.

PROFESSOR VIVIAN B. LEWES, "Fuel and its Future." Four Lectures.

March 9, 16, 23, 30.

WILLIAM BURTON, F.C.S., "The Nature and Structure of the Porcelains." Three Lectures.

May 4, 11, 18.

SHAW LECTURES ON INDUSTRIAL HYGIENE.

Dates not fixed:—

"The Removal of Dust and Fumes in Factories." By JOHN SCOTT HALDANE, M.A., M.D., M.R.C.P. (Edin.), F.R.S.

"The Dangers of Coal Dust and their Prevention." By W. E. GARFORTH, President of the Colliery Proprietors' Association of Great Britain.

"The Hygiene of the Pottery Trade." By WILLIAM BURTON, F.C.S., Chairman of the Joint Committee of Pottery Manufacturers of Great Britain.

"Child Workers and Wage Earners." By MISS NETTIE ADLER, Hon. Secretary to the Committee on Wage Earning Children.

HOWARD LECTURES.

Thursday evenings, at 8 o'clock:—

H. S. HELE-SHAW, LL.D., F.R.S., "The Navigation of the Air." Three Lectures.

March 19, 26, April 2.

JUVENILE LECTURES.

Two Lectures suitable for a Juvenile audience will be delivered on Wednesday afternoons, January 1 and 8, 1908, at 5 o'clock, by F. MARTIN DUNCAN, on "The Scientific Applications of the Cinematograph."

PROCEEDINGS OF THE SOCIETY.

THE EXAMINATIONS OF 1907.

The Society of Arts Examinations really commenced in 1857, when simultaneous examinations were held in Huddersfield and London, though a tentative examination was held in London in 1856. In the following year (1858) they were held at 58 different centres, nearly 300 candidates being examined. The numbers grew steadily till 2,160 was reached in 1869. The examination system was the outcome of the Society's Union of Mechanics' Institutions devised by Mr. Harry Chester in 1851. The object of the Union was to encourage the foundation of such Institutions, and to develop the educational facilities which they provided. The examinations were at first held through the agency of Institutions in Union with the Society, and only through their agency. Later on the Institution Centres were supplemented by a number of independent Examination Committees, and eventually such Committees were put on entirely the same footing as the Institution Committees, so that the necessity for the Union practically ceased, as the Institutions themselves changed their character and developed in various indepen-

dent directions. Still many of the most important of the Society's centres are even now associated with London and Provincial Institutions which were at one time, or still are, in Union with the Society of Arts.

The scope of the examinations at first was very wide, and included practically all the subjects of general education, but the field was restricted as other agencies took up various parts of the work. The establishment of the University Local Examinations in 1858 soon led the Society to abandon its purely literary subjects, while the examinations of the Science and Art Department, which commenced in 1861, led to the giving up of the scientific subjects. The result was that only the commercial subjects were retained, with the addition of—for some years—Domestic Economy and —down to the present date—Music. In 1871, when the Society's Council were considering the establishment of a system of Technological Examinations, they passed a resolution to discontinue the general examinations; but, on the application of some of the more important of the institutions in Union, they rescinded this resolution, and determined to continue the examinations for a further period. In 1879 the question of abandoning the examinations again arose, it being thought that the ground was covered by other agencies, and eventually it was decided to abandon them, and accordingly they were abandoned after 1880, no examination being held in 1881. Again, however, some of the Institutions where the examinations had been held protested, and, on further consideration, it was determined to continue the examinations.

Hitherto they had been free, but it was decided that an effort should now be made to make them self-supporting. They were accordingly recommenced in 1882, and a fee of 2s. 6d. was charged to each candidate. This fee is still charged to all candidates in the two higher stages. For a time it was insufficient to meet the costs of the examinations, but as the numbers grew, the fees just paid the expenses, and then produced a small profit. Now, however, with the increased number of stages, they hardly suffice to cover the cost.

No changes of any great importance were made in the system until 1901, when an Elementary Stage was added. This proved extremely popular, nearly 4,000 candidates entering in the first year. The number of candidates in the succeeding years is given in Table F, page 1165. When the examinations were first established, an elementary examination had been organised, the Society providing the material, papers and certificates; but the whole of the work and responsibility of the examinations was carried on by the local institutions. This system was never found very satisfactory, though it was useful when it was first established, and it was abandoned in 1894.

For some time the question had been under consideration of providing an examination of a character rather more advanced than the standard of the Society's general examinations, and in 1905 the system was to a certain extent reorganised, and an Advanced Stage established. Up to that time there had been only one Grade or Stage of each subject, but certificates of three classes were given, the successful candidates being arranged in First, Second, and Third classes. Under the new system adopted in 1905, three Stages were established—Advanced, Intermediate, and Elementary. In the Advanced and Intermediate Stages certificates of two classes are given, while the Elementary is merely a pass examination, and there are certificates only of one class. It was hoped that the standard of the Advanced Stage might be gradually raised so that it might supply the need of a higher standard examination, such as might be taken, for instance, by teachers. Up to the present, however, it has not been found possible, or desirable, to make any definite attempt to raise the standard, although, as the Tables, which will be found a little later on in this report, show, there has been a slight tendency to elevation.

When the examinations were re-organised in 1882, it was determined to offer, in addition to the separate subject certificates, a special certificate in General Commercial Knowledge, to anyone who had qualified, within a certain limited time, in a certain specified number of subjects. That this offer had small attractions to the candidates is shown by the fact that only a single application was made for such a certificate, during the 22 years the offer was open, and then only in the last year of the old system, 1904. In that year such a certificate was awarded to W. R. Richardson, of the Brighton Municipal School of Technology, who alone, so far as can be ascertained, had fulfilled the prescribed conditions. The offer still holds good, under the present system, but there has, as yet, been no single application.

In the Elementary Stage a few such certificates have been awarded, 41 in the eight

examinations which have been held since this Stage was established in 1901.

The examinations this year were held at 397 centres in the week commencing April 15th, and lasted from the Monday until the following Friday. The results were issued at the following dates:—Advanced Stage, July 15th; Intermediate Stage, August 10th; Elementary Stage, September 5th.

The Commercial subjects included, as usual, Book-keeping, Accounting and Banking, Shorthand, Typewriting, Economics, Précis-writing, Commercial Law, Commercial History and Geography, Arithmetic, Handwriting, and Modern Languages. The other subject of examination was Music, divided into Rudiments of Music and Harmony.

There were no changes this year in either the subjects or the details of the examinations. Last year some small alterations were made in the Shorthand examination, and the results of these appear to have been quite satisfactory. The system now appears to work with perfect smoothness, and it is not proposed to make any alterations for next year, the Programme for which was issued a few weeks ago.

As above mentioned, the number of centres at which the examinations are held is 397. Many of these are under the control of public educational authorities, and the Council would be glad to see the number of these increased. Although many of the centres, and some of these not the least important, are at institutions which are of the nature of private adventure schools, it is on the whole more satisfactory for the examinations to be under the control of public bodies, which cannot be supposed to have any interest in the success, or failure, of the candidates examined.

The Society this year awarded 28 Silver and 42 Bronze medals, the former in the Advanced Stage and the latter in the Intermediate. It also gave away money prizes to the value of £105, besides other prizes amounting in all to £30, provided annually by the liberality of the Clothworkers' Company.

At the request of the Army Council, the Council arranged to hold a special annual Examination in Shorthand for soldiers. The first examination was held on March 27th, at twenty-three centres in the United Kingdom, one in India, and two in South Africa. In the Advanced Stage (speed 140 and 120 words per minute), there were 8 candidates, of whom 3 obtained 2nd Class Certificates, and 5 failed. In the Intermediate Stage (100 and 80 words per minute) 32 candidates presented themselves, of whom 14 obtained 1st Class Certificates, 9 2nd Class Certificates, and 9 failed. A similar Examination has been arranged in Typewriting to commence next year.

The total number of candidates at the examinations of 1907 was 21,723 (Advanced, 4,279; Intermediate, 9,752; Elementary, 7,692). This is an increase of 364 upon the 21,359 candidates of 1906. The number of papers worked by these candidates was—Advanced, 4,815; Intermediate, 10,161; Elementary, 8,952. In addition to this there were 641 candidates examined in Music at the same time as those in the Commercial subjects, and 40 Shorthand candidates at the Special Army Examinations. In addition to these again there were 629 candidates in Colloquial Modern Languages, and 457 in the Practice of Music. The total number of candidates who were examined in all subjects by the Society of Arts during the year ending July last, was therefore 22,849.

The progress of the examinations since 1883, when they were re-organised and a fee was first charged, down to the present year, is shown graphically in the diagram on page 1162. The detailed results of the three stages of this year's examinations are shown in Table A page 1163, and the number of papers worked in each subject in 1905, 1906, and 1907 in Table B, page 1164.

The increase in numbers in the past and the current year has been very small. The new system introduced in 1905 resulted in a very large increase, from 17,771 in 1904, to 21,253 in 1905; in 1906, the number grew to 21,359, and this year to 21,723. Taking the number of papers worked, we find in the two upper stages a total of 14,976 this year, against 15,001 last, being a decrease of 89 in the Advanced, with 4,815 papers, and an increase of 64 in the Intermediate with 10,161 papers. In the Elementary Stage 8,952 papers were worked, an increase on last year of 525.

In Stages II. and III., Book-keeping is still the most popular subject, with 5,703 candidates, Shorthand being as usual, second with 4,323. French, which it is satisfactory to note has been steadily growing in popularity of late years, now takes the third place with 1,519 papers, Typewriting, with 925, being fourth. None of the other subjects reach such large figures. 553 candidates took up Arithmetic, 425 German, 322 English, 300 Accounting and Banking, 204 Précis-writing, 238 Commercial Law, and 197 Spanish. None of the other

subjects reached three figures. Hindustani, for which, when it was introduced in 1905, there were two candidates, attracted none this year. There were no candidates in Japanese or Chinese. In Stage III. there were none in Swedish, and only six in Stage II.

In the Elementary Stage the 7,692 candidates worked 8,952 papers, so that, as is always the case, a large proportion of the candidates in this, as in the higher stages, were content with a single subject. Book-keeping attracted the largest number, 2,666; next was Shorthand, 2,253. The next largest subject was French, for which there were 1,016 this year. In Arithmetic there were 1,006, a considerable increase on any previous year. Then comes Typewriting, for which 851 candidates presented themselves; in Handwriting and Correspondence, 575. In German the numbers were 341, Spanish 71. In Commercial Geography 136 candidates entered. Italian attracted 36 entries. In all 5,338 certificates were granted to successful candidates, and there were 3,614 failures.

The general character of the results, and the manner in which the various subjects were dealt with, may be estimated from Tables C and D (page 1164), which show the percentages of failures and successes for all the subjects in the two upper stages for the present year, and from Table E (page 1165), which gives percentages of successes and failures in all three stages for the last three examinations. The number of entries in some of the smaller subjects is insufficient for such calculations to have much value, but the percentages are given for the sake of completeness.

In the Advanced Stage the percentage of First-class is the highest yet reached. On the other hand the Second-class is a little lower, the failures being about the same as last year. The First-class percentage in the Intermediate Stage is higher than before, and that of failures lower. In the Elementary Stage there is also improvement. On the whole, therefore, there is progress.

Table F (page 1165) shows generally the progress of the Elementary Examinations since the foundation of that stage in 1901.

A report on the Practical Examinations in Music has been published in the *Journal*.* 457 candidates were examined—a decrease of 10 as compared with last year. These examinations have been carried on continuously since they were established in 1879 at the suggestion of Dr. Hullah. The numbers have never varied within very wide limits. In the first year 117 candidates were examined, The numbers increased gradually to 276 in 1891, and to 395 in 1895. The largest number yet examined was 566 in 1900.

* See *Journal*, July 26th, 1907, vol. lv., p. 893.

A report on the Vivâ Voce Examinations held this year has already appeared in the *Journal*.* 629 candidates entered—a falling off of 15 as compared with last year. These examinations were started in 1902, when 280 candidates were examined. The numbers rose to 681 in 1905. Since then there has been a slight falling off. Examinations were held in French, German, and Spanish. Last year there were some candidates in Italian. The Examiners all speak well of the results. The numbers in French and in German showed a slight increase, the number of German candidates being higher than in any previous year. In all three subjects the weak point of those Candidates who failed was in dictation. In conversation most of the successful candidates aquitted themselves very creditably, and some even brilliantly.

The examinations in Rudiments of Music and Harmony were carried on as usual at the same time as the commercial examinations, and the results appeared as part of the results of the Intermediate Stage. The total number of candidates was practically the same this year as last, as there was 641 this and 639 last year. There was a trifling increase in the number for Rudiments of Music, for which 413 candidates presented themselves, whereas last year there were 408. In Harmony there was a trifling decrease—228 as compared with 231. Of the 413 candidates in Rudiments of Music, 329 passed and 84 failed. Of the 228 candidates in Harmony, 164 passed and 64 failed. The examiner, on the whole, reports favourably on both sections of the examination.

In conclusion, the attention of both teachers and students may be drawn to the remarks of the various examiners on the results of last year. It will be found that these contain many valuable and helpful suggestions, and the work of the candidates year after year shows that far too little attention is paid to them. Teachers especially should study these remarks, and be guided by them in the instruction they give to their pupils. The remarks of each examiner follow his examination paper in the Programme for 1908.

* See *Journal*, November 1st, 1907, vol. lv., p. 1121.

THE COMMERCIAL IMPORTANCE OF TUNIS.

Tunis is overwhelmed by the unexpected needs which its riches have created. Originally it was a small agricultural country, depending upon its vines, cereals, and cattle. Everything was done in the least expensive manner, when a series of discoveries transformed Tunis from a strictly agricultural to a mining country. These discoveries commenced with the famous phosphates of Gafsa. Then the sudden rise in the value of zinc rendered the beds of calamine more important. In the neighbourhood of the phosphate beds of Gafsa the mines of Ain-Moulares, which are no less important, have been discovered. Farther north the mines of Kalaat-ed-Senam and of Kalaat-ed-Djerda, which are rather large, have been discovered. Five large iron mines are being worked at Hamennas, Djerissa, Slata, Nëbeur, and Nefzas. Attention is now directed towards the south, where manganese has been found in large quantities between Gafsa and Gäbes. Nothing has been said of the desert country at the extreme south, but the geologists are of the opinion that these mountains, being of the same origin of those at the north, contain the same proportion of minerals. Prospecting parties are being organised to investigate this region. According to the American Consul-General at Marseilles, the characteristic feature of all these mines is their size. It is expected that millions of tons will be extracted from the mines already discovered. Consequently, however far they may be from the sea, the groups which they form are sufficiently rich to justify the construction of a railway. As for the Gafsa mines, a line has been constructed from Mellaoin to Sfax; for the mines of Ain Safra, a line from Rudivef to Sousse is being made; for the mines of Kalaat-ed-Senam and Kalaat-ed-Djerda, a line has been constructed which goes from these points to Tunis, and branches to the mines of Hamennas, Djerissa, and Slatta are to be built; for the mines of Nebeur plans are being made to build a line to Bizerte; and for the mines of Nefzas, another line is being built which will be extended to Tabarka. This represents a railway system of nearly 622 miles built for the mines, which assure an exceptionally good traffic. For the present there is no question of a line to Gabes, but evidently the Tunisian Government has it under consideration, for plans are being made to spend £200,000 at this point, in order to create a deep-water port. The port will naturally relieve the railway. The lines already built are insufficient for the immense traffic. They have been called upon suddenly to handle traffic comparable to that of the largest French lines, and for which they are not properly equipped. The case of the line of Kalaat-ed-Senam is characteristic from this point of view. Four years ago it was built in view of a maximum traffic of 400,000 tons, which it was believed it would never attain. No one foresaw the rapidity with which—the use of it having spread in all European countries—the market for phosphates would increase. No one foresaw the extraordinary demands for iron which were to take place. The two phosphate mines of Kalaat-ed-Senam and Kalaat-ed-Djerda and the two iron mines of Slata and Djerissa, each wish to be assured of the transportation of 300,000 tons of mineral. Furthermore, the last district has shown that in a good year, the regions traversed have 100,000 tons of cereals for exportation. Consequently, this railway has 1,300,000 tons of goods to transport, but this it is impossible to do. The rails are too light, the sidings too few, workshops too small, and the rolling stock insufficient. The Tunis railway station, much too small, is frequently dangerously blocked. The port of Tunis is considered no longer sufficient and its enlargement is advocated. In a report to the Director of Public Works of the Regency, it is shown that Tunis ought to expend, in the next ten years, £5,000,000 in public works, in order to aid in the development of the country, Tunis can obtain £2,000,000 from her ordinary resources, the rest must be secured by means of a loan. The utility of public works was never more evident. The financial condition of the country is so good that each year its budget has been liquidated by large surpluses, which in 1903 exceeded £400,000.

HOME INDUSTRIES.

Textile Machinery.—The exports of British textile machinery last month show continual progress in value. The total for October, according to the Board of Trade returns, is £752,526, as against £657,170 for the corresponding month of last year, and £583,883 for October, 1905. The total for the first ten months of the current year is £6,630,155, as against £5,467,880 for the corresponding months of 1906, and £4,495,520 for those of 1905. The gain for the current year shows, therefore, an increased ratio both in the month and in the ten months. The increase is no doubt due in part to the necessary increase of renewals, with the continued increase of plant. Taking last month's exports, those to Germany show the largest increase, the value being £127,281, as against £76,632 in October, 1906. The value of the exports to "Other countries in Europe" has increased from £136,180 to £172,450, but the exports to France show a slight falling off, as do those to the United States. The exports to "Countries in South America" show a large increase, but to British India there is shrinkage from £191,496 to £171,623.

The Motor Industry.—There seems to be a considerable slackening in the demand for motor cars, and many factories in Coventry have been put on short time, large numbers of men being discharged from the offices and works. The condition of the textile machinery and the motor-car industries, says the *Manchester Guardian*, presents an interesting contrast in methods of dealing with a sudden expansion of trade. Two or three years ago the demand for motor-cars suddenly increased at an extraordinary rate. Nearly all the manufacturers, carried away by the boom in their business, hastened to build immense factories to deal with it. As might have been expected, although the demand continued to increase, the rate of increase was by no means kept up, and this year many motor-car makers are left with large stocks of costly cars on their hands. The textile machinists have had a similar rush of orders, but we do not hear of any textile machinery factories being erected four or five times the size of the existing ones. The machinists prefer to extend slowly, and people who want textile machinery must wait until existing works can catch up to their orders. They are not to be caught, as it would seem the motor-car makers have been, with a huge output and a poor demand. It may be stated in this connection that, according to statistics just published, there were 148 strikes and eight lock-outs in the German textile industry last year, which affected 384 establishments, and 76,675 workers. The largest number of strikers at any one time was 29,215. The disputes were all short lived, the duration in the majority of cases being less than a month. The returns give no particulars as to the results of these disputes, but it is known that most of them failed. The German manufacturers are well organised, and when a dispute leads to a strike in one factory a general lock-out usually takes place all over the affected district.

The Iron Trade.—The position of the iron market at the present time is peculiar. There is great depletion of the stocks of crude iron. They are lower than they have been for fifty years. Twenty years ago, according to figures taken from the *Statist*, there were 1,250,000 tons of Scotch G.M.B. in the Glasgow warrant stores where now there are 1,300 tons; there were 650,000 tons of Cleveland No. 3 foundry iron in Middlesbrough warrant stores where to-day there is only 110,000, and where last year there were 700,000 tons. At the end of December last there were 622,000 tons of pig iron in the warrant stores of Glasgow, Middlesbrough, and Cumberland, where to-day there are only 127,000 tons. Yet the price of Cleveland warrants is 10s. to 12s. per ton lower than it was when the stock was over half a million tons. And while Cleveland warrants have come down to about 52s. and even under—as compared with 63s. 6d. when the boom was on—there were sellers last week of three months' iron at 2s. 6d. to 3s. per ton under the "spot" price, a striking indication of the feeling that warrants must come down very heavily before long. And yet there are only 110,000 tons in the warrant store, and there is no excess of Scotch iron. Trade and official statistics continue to show large shipments of iron, and trade reports say that makers are sending out their iron as fast as they can make it. But whatever activity there may be is in connection with the fulfilment of contracts entered into when the boom was on. Little or no business is coming in from anywhere, nor is much expected in the near future. On the contrary, a condition of considerable depression is anticipated. Furnaces and factories are still busy, but they are rapidly completing their orders. The industrial activity in Germany and the United States did much to sustain our markets, but in both countries trade is beginning to decline. But it must be remembered that it does not follow that declining trade will mean immediately corresponding reduction of production of iron in Germany and America, and of production continues whilst home consumption diminishes our markets are likely to be flooded with low quotations of German steel and Belgian ore. On the Tyne and Clyde German ship plates are already pressed for sale at large reductions on the prices of English and Scotch makers; and if they are not being freely bought it is probably because the shipbuilders have already satisfied their present requirements. Then there is the enormous American production which will have to be got rid of. Unless production is cut down sooner and more largely than is anticipated America must be a large exporter of manufactured steel as well as of crude iron. At home, too, activity is rapidly diminishing. In the shipbuilding trade there is great and growing depression. Many yards will be almost or entirely idle during the winter months, and

thousands of hands are being discharged as contracts are being completed. The over-production in the shipping world is telling at last, and the re-action, long foreseen, has arrived. It might perhaps have been delayed a little longer if prices of shipbuilding material had not been so high recently, but it was bound to come, as it must come in all trades where the supply greatly exceeds requirements. It is true that of late steel manufacturers have been much helped by the increased application of steel in house building, but the building trade is in a state of depression from which it is not likely to emerge for some little time to come. The present outlook for the iron trade is much less favourable than it has been for some years past.

Economy in Coal Production. — If a writer who signs himself "An Old Collier," is correct much remains to be done in improving the methods of conveyance of coal from the working face to the bottom of the pit shaft. His contention is that owing to the bad and intricate roads over which it has to be conveyed the production of coal per man employed is much less than it might be, whilst the cost is proportionately greater. "I know," he writes, "instances where seven men and lads work in one gang, but only three of these are at the working face, the other four being required to fill and 'waggon' the coal from the face to the main haulage road. First you very often have to let the waggons down a short brow or bay from the face, then run them from 50 to 300 or 400 yards to a jig-brow; then you may have to follow them and again 'waggon' them on another road, and in some cases they have to be wound up a gradient of one in three or three and a half for a distance of sixty yards. In same places the wheels of the waggons will be scotched; in others the men must exert all their strength to keep the waggons moving. The roofs of the roads are often very low, and the waggons will rub against a few pit-props at one place and against the sides of the 'goff' at other points. The bars supporting the roof have broken here and there, and the roofing has sagged, so that even if it does not catch the waggon, it will catch the piled up coal on the waggon, and worse still, the waggoner's fingers." "An Old Collier" suggests that in addition to the accidents in the haulage roads reported by Inspectors of Mines there are many minor accidents due to neglect of the roads that are unreported. It would be interesting to have the opinion of experienced mine managers upon these allegations and, assuming them to be well founded, why it is that the present system, which must be wasteful as well as dangerous, is continued.

Linoleum Manufacturers and Retailers. — Changes are taking place in the relations of wholesale linoleum houses and their customers. The tendency seems to be to eliminate the middleman in the shape of the wholesale houses, by discontinuing special discounts, and dealing direct with the retail trade. In this the leading linoleum companies are only following the example of the Worcestershire, Yorkshire, and Scotch carpet firms and companies, in refusing any longer to extend special advantages to wholesale houses. These houses are endeavouring to resist the change by approaching Continental makers, mostly German, with the object of supplying foreign makes of floor coverings in place of British, but it is not thought likely that foreign competition will in this trade be a serious factor. The objection to dealing direct in other departments of the textile trade is that it necessitates the opening of a number of small accounts, swelling expenses for travelling and carriage, and increases the risk from bad debts. But it is said that in the case of floor coverings these objections do not exist, because the bulk of the retail furnishing trade is in the hands of a comparatively small number of large retail houses.

The Retail Oil Trade.—A trade journal raises the question whether the tendency to shrinkage in the consumption of oil which has been apparent of late is likely to be permanent or temporary. In both 1905 and 1906 considerably less oil was used, whilst this year there has been little change; lessened receipts of oil from Russia being counterbalanced by larger ones from America. The price during 1905-6 was mostly over sixpence per gallon in barrels at the ports of entry, and this rate is considered by the Trade to be fairly moderate. If burning oil goes much above this limit, the competition of the "slot" gas meter begins to be formidable. During the present winter the wholesale price is expected to range between 7d. and 7½d. for American oils and this is likely to lead to smaller consumption in towns where the slot gas-meter system is in use. The tendency anyway is to use less and less oil for heating and cooking, and probably before long the only large consumption will be in illumination. The quantity of illuminating oil used in Great Britain during twelve months ranges from 150 to 170 million gallons, but in 1903-4 it was nearly 200 million gallons. Any rapid falling off in the consumption would mean a considerable reduction in prices, for producers must get rid of this part of their petroleum products, and the prices obtained for spirit would enable them to sell it a good deal cheaper than they do at present.

GENERAL NOTES.

TANNIC ACID.—There is a large quantity of tannin bark made in Bône (Algeria), and Mr. Vice-Consul Scratchley suggests (Cd. 3727-18) that it might be advantageous to treat the bark so as to extract the tannic acid, and to ship it in the form of extract, instead of sending it away in its natural state. The tannin bark from the cork-wood tree contains about 12 per cent. of acid, but that of the green oak has

only 6 to 7 per cent. If the tannic acid were extracted, a great gain would result in the bulk of the matter shipped. The leaves of the lentisk, or mastic bush, which cover an immense area in the forests, could also, the Vice-Consul says, be treated by the same process. The leaf is sometimes sent away under the name of sumach, which it somewhat resembles. Cork-wood waste having fallen considerably in value, the Vice-Consul suggests that it might be a profitable undertaking to reduce it to a powder and ship it in pressed bales. The powder is much easier to press than the bits of cork of different forms and sizes. As the waste in bags makes a very bulky parcel for little weight, shippers do not care to stow it in the hold unless the freight is high, and the buyers do not like waste to be shipped as a deck cargo.

MALAGA WINES.—Malaga wines, which have an excellent reputation in almost every market of the world, find but an insignificant sale in the United Kingdom. Referring to the point in his report on the trade of Malaga (Cd. 3727-201), Mr. Consul Haggard attributes it to the wines being almost unknown in this country, both as medicinal and dessert wines. In his opinion there is no doubt that were the wine called muscatel (which is made from the same grapes as the raisins of that name) known here it would soon achieve the reputation he thinks it deserves, not only on account of its richness in flavour, but also on account of its medicinal qualities. Besides the Spanish red from the central provinces, of which considerable quantities are shipped from Malaga, a trade is beginning in the dark Malagas, which are giving good results for the colouring of whisky. A steady increase in the export of this wine is perceptible every year. Owing to the rise in prices brought about by the fall in exchange, exports, especially in Spanish reds, have decreased considerably.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Nov. 18...East India Association, Caxton-hall, Westminster, S.W., 4 p.m. Mr. Welinkar, "The Problems of Higher Education in India."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. Mervyn Macartney, "The Present Condition of St. Paul's Cathedral."

Junior Institution of Engineers, 25, Great George-street, Westminster, 8 p.m. Presidential address by H. Gustave Canet on "The Latest Improvements in French and English Modern Artillery."

London Institution, Finsbury-circus, E.C., 5 p.m. Mr. Eric S. Bruce, "The Coming of the Aeroplane."

TUESDAY, Nov. 19...Statistical (in the ROOMS OF THE SOCIETY OF ARTS, John Street, Adelphi, W.C.), 5 p.m. Presidential address by The Right Hon. Sir Charles W. Dilke, Bart, M.P.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. H. T. Ker's paper, "The Extension, Widening, and Strengthening of Folkestone Pier." 2. S. H. Ellis, "The Tranmere Bay Development Works."

Photographic, 66, Russell-square, W.C., 8 p.m. Mr. E. Seymour, "Flower Photography."

Anthropological, 3, Hanover-square, W., 8½ p.m.

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4½ p.m. Dr. J. M. Bell, "The Mineral Wealth of New Zealand."

WEDNESDAY, Nov. 20...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Opening address of the 154th Session by Sir Steuart Colvin Bayley, Chairman of the Council.

Meteorological, 25, Great George-street, W., 7½ p.m. 1. "The International Balloon Ascents, July 22nd to 27th, 1907." Reports by Mr. W. H. Dines, Mr. J. E. Petavel, Mr. W. A. Harwood, Captain C. H. Ley, and Professor W. E. Thrift. 2. "Discussion of the Meteorological Observation made at the British Kite Stations, 1906-1907." By Miss M. White, Mr. T. V. Pring, and Mr. J. E. Petavel.

Geological, Burlington-house, W., 8 p.m.

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. E. W. Nelson, "François Watkins' Microscope." A reply to Prof. Porter's and Mr. Everitt's criticism upon my paper, "On the Limit of Resolving Power for the Microscope and Telescope." 2. Mr. J. W. Gordon, "Mercury Globules as Test Objects for the Microscope." 3. Mr. E. Moffat, "Light Filters for Photomicrography."

United Service Institute, Whitehall, S.W., 3 p.m. Brig.-Gen. Sir H. S. Rawlinson, "Night Operations."

Entomological, 11, Chandos-street, W., 8 p.m.

THURSDAY, Nov. 21...Royal, Burlington-house, W., 4½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. W. C. Worsdell, "Abnormal Structures in Leaves, and their Value in Morphology." 2. Mr. J. G. Otto Tepper, "Specimen Preservation in Australian Museums." 3. Mr. S. G. Dunn, "Revision of the genus *Illigera*, Blume." Exhibitions: Mr. G. W. Anderson, "Luminous Larva from British Guiana." 2. Professor A. Dendy. Living Specimens of *Peripatus* from South Africa. 3. Mr. G. C. Druce, *Linaria Serenaria* and other British Plants.

Chemical, Burlington-house, W., 8½ p.m. 1. Mr. S. P. U. Pickering (*a*) "The Interaction of Metallic Sulphates and Caustic Alkalies." (*b*) "The Chemistry of Bordeaux Mixture." 2. Messrs. M. O. Forster and H. E. Fierz, "Aromatic Azoimides. Part III.—The Naphthylazoimides and their Nitro-derivatives. 3. Messrs. T. M. Lowry and E. H. Magson, "Studies of Dynamic Isomerism. Note on the Action of Carbonyl Chloride as an Agent for Arresting Isomeric Change." 4. Mr. S. P. U. Pickering, "Emulsions." 5. Mr. H. G. Denham, "The Electrometric Measurement of the Hydrolysis of the Salts of Anilinium, Ammonium, Aluminium, Chromium, Thallium, Zinc, Magnesium, Cerium, Thorium, Nickel, and Cobalt."

London Institution, Finsbury-circus, E.C., 6 p.m. Mr. Bryan Corcoran, "St. Olave's, Hart-street, and the Old City Walls."

Historical, Lecture-hall, Field-court, Gray's-inn, W.C., 5 p.m. Professor C. H. Firth, "The Ballad History of Henry VII. and Henry VIII."

Numismatic, 22, Albemarle-street, W., 6½ p.m.

FRIDAY, Nov. 22...Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

Physical, Royal College of Science, South Kensington, S.W., 5 p.m. 1. Mr. S Skinner, "On Singing Sand from New England." 2. Mr. L. Bairstow, "Exhibition of a Micromanometer." 3. Mr. Vernon Boys, "A Diabolo Experiment." 4. Professor H. A. Wilson, "Exhibition of a Gyroscope Illustrating Brennan's Monorailway."

CONTRIBUTIONS TO THE READING-ROOM.

The Council have to acknowledge, with thanks to the Proprietors, the receipt of the following Transactions of Societies and other Periodicals.
